Friday Next.

Odontoglossum crispum (Alexandræ) and Cattleya aurea.—By order of Mr. THOMAS ROCHFORD, of Turnford Hall Nurseries, Broxbourne.

MESSRS. PROTHEROE and MORRIS are favoured with instructions to SELL BY AUCTION, at their CENTRAL SALE ROOMS, 67 and 68, CHEAPSIDE, E.C. on FRIDAY next, JANUARY 7, 1898, at Half-past Twelve o'clock precisely, a wonderful importation of about 15,000 ODONTOGLOSSUM CRISPUM of the very finest strain, forming probably one of the grandest consignments ever received. The entire importation has been collected by Mr. John Carder, who made a special journey to obtain these plants on Mr. Rochford's behalf. Mr. John Carder's name is well known as a sender of Odontoglossum crispum, his consignments in former years having produced such fine varieties, giving him a reputation not excelled by any other collector. The consignment will include a large number of masses of unusual size, and all are in splendid condition, the greater portion showing strong breaks. Mr. Rochford will also include in the same sale 300 CATTLEYA AUREA, very fine plants, all semi-established and unflowered; unquestionably a very fine batch of this extremely beautiful Orchid.

On view morning of sale. Catalogues may now be had on application to the Auctioneers, 67 and 68, Cheapside, E.C.

N.B.—Messrs. Protheroe and Morris have personally inspected the above importation, and can strongly recommend the plants to intending purchasers, as they are undoubtedly in the best possible condition.

Wednesday Next.

A selection of choice named Standard and Dwarf Roses, Standard, Dwarf Trained, and Pyramid Fruit Trees, Border Plants, Palms, Ornamental Shrubs and Trees, Japanese and other Lilies, Bulbs, &c.

MR. J. C. STEVENS will SELL the above BY AUCTION, at his GREAT ROOMS, 38, KING STREET, COVENT GARDEN, on WEDNESDAY next, Jan. 5, at Half-past Twelve precisely.

On view morning of sale and catalogues had.

Thursday Next.

An immense Collection of over One Thousand Lots of HARDY PERENNIALS.

MR. J. C. STEVENS will SELL the above BY AUCTION, at his GREAT ROOMS, 38, KING STREET, COVENT GARDEN, as above, at Half-past Twelve precisely.

On view morning of sale and catalogues had.

Fifty Nurseries, Market Gardens, Florist and Seed Businesses to be disposed of.

MESSRS. PROTHEROE and MORRIS'S HORTICULTURAL REGISTER contains full particulars of the above, and can be obtained gratis at 67 and 68, Cheapside, E.C.

RICHARD SMITH & Co. WORCESTER

NEW CHRYSANTHEMUM,

"JOSEPH CHAMBERLAIN."

A magnificent crimson seedling from Edwin Molyneux, by far the best novelty of the season, and a grand acquisition. I have much pleasure in stating that I have secured the entire stock of this fine novelty from the raiser, Mr. H. Weeks, of Derby. For price and particulars of other fine novelties of the same raiser see Catologue, post free on application.

NORMAN DAVIS,
CHRYSANTHEMUM NURSERIES,
FRAMFIELD, SUSSEX.

Situations Wanted.

Advertisements under this heading are charged 1s. each, four lines (32 words), and 3d. per line after.

THREE INSERTIONS FOR THE PRICE OF TWO!

COPIES OF THE "GARDENERS' MAGAZINE," POST FREE, TWO PENCE HALF-PENNY.

BARR and SONS have on their Register several competent HEAD and UNDER GARDENERS. They will be pleased to furnish full particulars on application.—12 and 13, King Street, Covent Garden, London.

FOREMAN, General.—Mr. Hayler, Kingston Lisle, Wantage, can with confidence recommend W. Murphy as a good practical all-round man; leaving through reduction; abstainer.—Address as above.

GARDENER (Head).—Wm. Fyfe, Lockinge Gardens, Wantage, would have great pleasure in very highly recommending George Ellwood, foreman here, as a thoroughly trustworthy and practical man.

GARDENER (Head Working), married, no children; life experience where fruits, flowers, and vegetables are required the year round; dairy land; charge of house if required; left through death; good references.—Address W. CORNWELL, 9, Windermere Road, Upper Holloway, N.

GARDENER (Head Working); age 34; two children; life experience in first-class establishments; well up in all departments; first-class testimonials.—BEARDSLEY, Grove Cottage, Golder's Green, Hendon.

GARDENER (Head Working, or good Single-handed); married; practical experience in all branches; good references; leaving through no fault; age 36.—Address R. WATERS, The Moat, Soham, Cambs.

GARDENER (Head Working); age 36, married, no family; life experience in orchids, stove, vines, &c., flower and kitchen gardens, land and stock; leaving through establishment being sold; good character.—DOWNHAM, The Cottage, Westland, Tilehurst Road, Reading.

GARDENER.—Experienced, competent for growing nice flowers and vegetables, has many prizes for stove, greenhouse plants, &c.; management of all-round general work as responsible man; age 37; good references.—Write to B., 11, Holmes Road, Kentish Town, N.W.

GARDENER (Head Working).—Situation desired as above; good all-round practical man; married; aged 40; life experience; highest references from the Hon. Mrs. Dudley Pelham; also Mr. W. Drover, Fareham Nurseries, Bedford Norton, St. Lawrence, I.W.

GARDENER.—Advertiser (aged 39, married) now in London neighbourhood, seeks permanent situation; he has a good practical training.—Full particulars sent on application to E. L., care of Dickson's Nurseries, Chester.

MR. MALCOLM C. INGLIS, who has given up his establishment at Glenfarme, wishes to recommend W. T. Street to any lady, nobleman, or gentleman requiring a first class GARDENER.—Address W. T. STREET, Deal, Kent; or to Malcolm C. Inglis, Esq., 38, Dame Street, Dublin.

GARDENER (Single-handed or otherwise) age 28; married, no children; 14 years' experience in al branches; good reference.—WALTON, 27, Affleck Street, Pentonville, London.

REV. H. H. MILES can highly recommend his gardener, who has been upwards of fourteen years in his service; thoroughly understands vines, glass, &c.; leaving in consequence of establishment being broken up.—Address, J. MEIKLEHAM, Dunfield Lodge, Kington, Herefordshire

RICHARD SMITH and CO., beg to announce that they are constantly receiving application from Gardeners seeking Situations, and that they will be able to supply any Lady or Gentleman with particulars, &c.—St. John's Nurseries, Worcester.

Herbaceous and Alpine Department.

YOUNG MAN (age 22) with good knowledge of above, would like to take charge of collection of same; private preferred; abstainer; good references.—WILLIAM SHEPPARD, 94, Waverley Place, Gigant Street, Salisbury.

YOUNG MAN (aged 21) seeks re-engagement as UNDER GARDENER; five years' experience; good references given.—F. PRIOR, Bowden Lodge, Totnes, South Devon.

YOUNG MAN (good position), desires situation in nursery; quick, willing; 18s.; references.—STANWELL, Ipsden, Wallingford.

IMPORTANT NOTICE.

AN EMPLOYMENT REGISTRY DEPARTMENT IS CONDUCTED IN CONNEXION WITH THE "GARDENERS' MAGAZINE," AND THE CHARGE FOR AN ADVERTISEMENT ***INCLUDES A FREE ENTRY ON THE REGISTER FOR ONE MONTH.*** IF NOT SUITED AT THE END OF THAT TIME, AND IT IS DESIRED THAT A NAME SHOULD REMAIN, IT WILL BE CONTINUED FOR A FURTHER PERIOD UPON RECEIPT OF A REQUEST. IMMEDIATE NOTICE MUST BE GIVEN WHEN AN ENGAGEMENT IS SECURED.

A List of Gardeners on the Register will be supplied upon application to the Publishers if a stamped envelope is forwarded, addressed 148 and 149, Aldersgate Street, London, E.C.

PEARSON'S CHEMICAL MANURE.

Every Gardener and Exhibitor who tries this becomes a regular customer; so confident are we of this that we will send a SAMPLE TIN (enough to dress 50 pots) GRATIS to any reader of this paper who will cut out and send this advertisement with three stamps to cover postage. Address—

NOTES OF THE WEEK.

THE NEW YEAR.

The commencement of the new year affects us in various ways, and no one who takes an active interest in the garden, or, indeed, in anything that has a direct bearing upon the welfare of the community, can escape being influenced. In a strictly philosophical view of the matter, one day is as important as another; but the sentimental view of the season is of great practical value, as prompting wholesome reflections and affording a favourable opportunity for making new resolves, and preparing for the conflicts in the world of horticulture that are in prospect. Whether the year on which we have entered will be a good or bad one, as compared with previous years, it is impossible to say; but we enter it with a spirit of hopefulness, and strengthened by the knowledge that there is an expanded and expanding interest in the various aspects of the art of gardening. We have not in prospect any event of exceptional importance to horticulturists within the United Kingdom, but the Ghent Quinquennial, to be held during the coming spring, will afford some compensation, and give our countrymen another opportunity of becoming acquainted with the ornamental aspects of Belgian horticulture. If there are none but exhibitions of the customary character to be held during the year, they will be sufficiently numerous to provide plenty of work for those who take part in them, and of these the most important will be sufficiently comprehensive to ensure an adequate representation of British horticulture. The Royal Horticultural Society will hold the two exhibitions which for several years past have occupied an important position in its annual programme; the special societies, which have greatly increased in strength and activity of late years, will amply vindicate the flowers in which they are respectively interested; and we anticipate with much interest the horticultural gatherings in the great provincial centres. The reward the gardener will obtain for the care and unremitting attention bestowed upon the objects of his care can have no estimate placed upon it at the present time. The year 1898 should be remarkable for its crop of fruit, for last year the crops were in most cases so light as to in no way unduly tax the energies of the trees, and the magnificent weather experienced early in the autumn was so favourable to the ripening of the wood, that the embryo flower buds are so perfect, as to justify a spirit of hopefulness as to the ultimate results, provided the climatic conditions are favourable. So far they have not been such as we could wish; we have had no winter as yet, and if the winter does not come the spring will, and unless some early check is imposed upon awakening vegetation the morning frosts and east winds will not fail to do more or less damage. As this is a season for making new resolves, we would urge upon our readers the importance of being well in advance with all gardening operations, due consideration being in all cases paid to the district, soil, and weather, and to remember that this can only be done when the seeds are purchased early in the year. By ordering seeds now the cultivator places himself in a position to sow the several crops at the proper time, and, what is not less desirable, helps to reduce the strain which late purchases impose upon those engaged in the seed trade. With regard to ourselves there is no occasion to speak at length. The ever-increasing number of readers is the best possible proof that the vigorous policy characteristic of the journal is appreciated by all classes of horticulturists, and with such gratifying evidence of appreciation our readers may be well assured that we shall in no way relax our efforts to maintain the GARDENERS' MAGAZINE in the position it occupies as the foremost exponent of horticulture in the United Kingdom.

VITALITY OF SEEDS.

Notwithstanding the immense advance that has of late years been made in the several branches of biological science, a difference of opinion continues to exist amongst botanists with regard to the condition of the protoplasts of resting seeds, in which signs of life are indistinguishable for a considerable period. On the one hand it is assumed that the essential elements of the cell undergo during the period of inertness some slight, although imperceptible, alteration, with or without a gaseous exchange with the surrounding atmosphere. On the other side it is maintained that metabolism is completely arrested in protoplasm when the seeds are perfectly dormant, and that so long as they remain in that state it has no power of internal adjustment to external conditions. Much might be said on either side in support of the views held, but the results of carefully-conducted experiments appear to show that there is full justification for the opinion held by those who contend that there is during the resting period a cessation of protoplastic activity. The experiments of the late Professor Romanes a few years since have an important bearing upon this point. Professor Romanes submitted in glass tubes various seeds to high vacua for a period of fifteen months, and other seeds were subjected to high vacua for three months, and then transferred to other tubes charged with various gases, and it was found that neither a high vacuum nor exposure for a year to either of the gases employed had any appreciable effect upon their germinative power. The experiments of Romanes proved to demonstration there could have been no respiration, but they were hardly conclusive with regard to chemical interactions within the cells, and to clear up this point Messrs. H. T. Brown and F. Escombe subjected seeds of twelve plants of widely different character to a temperature below that at which chemical reactions take place. From a recent communication to the Royal Society we learn that the seeds of Avena sativa, Convolvulus tricolor, Cucurbita Pepo, Cyclanthera explodens, Funkia Sieboldi, Helianthus annuus, Heracleum villosum, Hordeum distichon, Lotus tetragonolobus, Pisum elatius, Impatiens balsamina, and Trigonella fœnum-græcum, were selected for the purpose of experiment. Through the kindness of Professor Dewar in putting his laboratory at the disposal of the experimentalists, they were able to ascertain how far the subsequent germinative power of the seeds is affected by prolonged exposure to the very low temperature of liquid air. The seeds, we are told, "were enclosed in thin glass tubes, were slowly cooled and immersed in a vacuum-jacketed flask containing about two litres of the liquid air, which was kept replenished so as to submit the seeds for one hundred and ten hours to a temperature of from 183 to 192 degrees Centigrade." After this treatment they were slowly thawed, a process which occupied about fifty hours, and it was subsequently found that after having been submitted to this low temperature, they germinated as freely as seeds from the same stocks that had not been treated. The great value of the low temperature experiments carried out by Messrs. Brown and Escombe, consists in the fact that processes of autoxidation are rendered impossible at the temperatures to which the seeds were subjected, and consequently the protoplasm in resting seeds is regarded as existing in an absolutely inert state, devoid of any trace of metabolic activity, and yet conserving the potentiality of life. These experiments are of importance as indicating the possibility of maintaining the perfect stability of protoplasm when once it has reached the resting state, provided the low temperature is maintained, or in other words, of keeping the seeds for an indefinite period, without their vitality being impaired.

WORMS.

Although worms are a great nuisance, and do a large amount of harm when they intrude into the horticulturist's pots and pans, upsetting and burying his choicest seedlings, and disturbing and weakening larger plants by burrowing among their roots and choking up the drainage, they, like many other nuisances, are highly beneficial agents in their proper place, which in this case is the open soil. At this season of the year especially it is wonderful to observe how speedily the fallen leafage disappears from the surface. The dead leaves may be lying an inch thick about the garden one week, and the next, without the aid of a broom or rake the bulk, if not all, will have been silently drawn down the myriad burrows of the ever-busy worms. It is very interesting to watch the process, though the would-be observer must go gently about on tiptoe unless he wishes to see a number of rapidly-vanishing heads instead of the worms busily engaged in the work in question. Adopting this precaution, or waiting quietly awhile to restore confidence, we shall see the pointed heads gradually emerge, or re-emerge, and after giving it a tentative swing round Master Worm will slowly lengthen out, bit by bit, his tapering snout so to speak feeling the way until presently a leaf is reached. Then begins a series of pulls and tugs, until literally hook or by crook, the dainty morsel is drawn to the hole. Now commences the serious business of getting perhaps a stiffish two-inch morsel into a cavity only a quarter of an inch across. Getting the edge close to the cavity, a succession of pulls gradually curls up the leaf in a sort of funnel, and this once done the rest is easy, and the leaf is buried, eaten, and digested at leisure. Clearly, were not some such provision as this to exist, the surface soil would become simply covered by the decaying leaves, choking its aerating cavities and breeding stagnation instead of the active life which is encouraged by this method of conveying the leaf material in an easily assimilated form once again to the roots. It is therefore, to be regretted that the cultivation has been advocated of worm-eating slugs (Testaculas), for the purpose of destroying these (in their proper place) beneficial creatures. Already the race, prolific as certainly is, has enemies galore; many carnivorous insects besides Testacella, as, for example, the centipede, prey upon the worm, and the whole host of birds combine in considering it a tit-bit, so that the industrious leaf-sexton has good need to exercise caution before stretching his full length from his burrow to find a meal which nothing else but a fungus would be able to thrive upon. Taking the worm altogether, it is certainly a most ill-used animal all round, his special and proper domain is ploughed, and harrowed, and dug, and hoed, in such a drastic fashion, that he is liable at any moment to be crushed, cut up, and otherwise demolished to such an extent that beneficent Nature has hindered his extinction by rendering his cleanly-cut sections capable of regenerating fresh heads and tails, and so starting anew as a family instead of becoming a defunct individual. Then, besides the energetic gardener and agriculturist, he has to pay tribute to the angler in an exceedingly unpleasant fashion; and although we may assume that his nerves are no quite so sensitive as our own, it is extremely doubtful if any sense of gratitude is felt when the truant schoolboy shirks his proper studies in order to "teach the worm to swim," with a bent pin or a barbed hook to aid it in its first atempt at natation.

PRUNING ORNAMENTAL TREES.

In a note, entitled "Beauty in a Tree," which appeared in our issue of November 20, it was pointed out that upon the amount of intelligence the pruner, now at work in the suburbs, puts into his work, will depend the beauty of the tree next summer. We are reminded of the dark ways of some tree pruners by what was once a magnificent line of elms on the border of an open space in a charming village in one of the home counties. The trees were all topped at varying heights; in some cases several feet of naked stem, denuded of branches, were left standing above the lower branches; and for years these trees were unattractive objects, and they have never recovered from the cruel and unnatural treatment to which they were subjected. We suppose that the pleasure some persons appear to find in the trimming of ornamental trees in this sad fashion is based upon a feeling that trees growing in a quite natural way must be capable of some improvement by art; and as pruning is usually acknowledged to be useful in developing certain points in a fruit tree, a like good purpose will be served by the free use of the knife and saw upon an ornamental tree. But the comparison does not hold good, since the objects aimed are essentially different. Pruning, at least all useful pruning, as applied to fruit trees, is for the purpose of adding to, diminishing, or otherwise regulating the fruitfulness of the tree; and this, in many cases, is effected to the acknowledged diminution of the growth, luxuriance, and beauty of the tree, so far as spread of branches and prodigality of foliage go. But even here, the pruner who prunes only for the sake of using the knife, not unfrequently goes too far, prevents the perfect maturity of the growth, and hastens the decline of the tree by depriving it of the fair proportions which Nature has established between the leaf and the roots. We imagine that the practice complained of is a want of perception of what is really beautiful in an ornamental tree. It seems to be indisputable that no one who has any perception of what is really beautiful in Nature could ever doubt for a moment that a fine elm or oak, which has never been touched by the knife, is the most perfect standard of sylvan grace, symmetry, dignity, and finely-balanced proportions that it is possible to conceive. A pollard willow should be the very type and model of beauty in the eye of the champion of the indiscriminate use of the pruning saw. What Nature has specially shaped for the delight of the eye, and as a fine suggestion to the spiritual sense, can be seen in a beautiful tree, and man should not lightly undertake to remodel, or clip away any of its fair proportions.

The Gardening Year Book for 1898 is now published, and may be obtained through the usual channels in any part of the United Kingdom or direct from the office, as may be desired. As this highly-popular publication has reached its fortieth year it is by far the oldest of the annuals relating to gardening, and a glance at its well-filled pages will be sufficient to show that there has, in the preparation of the edition for the current year, been a full appreciation of the requirements of both amateur and professional horticulturists, and also that no effort has been wanting to maintain the remarkable degree of popularity the publication has enjoyed for so long a period. As in previous issues the plants, flowers, fruits, and vegetables introduced during 1897 are concisely recorded, the year's work in the garden is fully discussed, and a new set of reminders for the daily work has been prepared for the almanack pages. In a series of brightly-written chapters the management of the conservatory, greenhouse, orchid houses, fruit houses, flower garden, orchard, kitchen garden, and indoor and outdoor ferneries is dealt with, and under separate headings the cultivation of all the more important plants, flowers, fruits, and vegetables is fully described and the most distinct and useful varieties enumerated. The directories of horticultural societies and public parks, which have formed such popular features since their introduction a few years since, have been thoroughly revised, and are remarkable for their completeness and accuracy. The work is freely illustrated, the illustrations including coloured plates of popular plants.

The Eastern Thorn.—Mr. E. Beckett, of Aldenham House Gardens, writes, in reference to this handsome thorn: I was much interested in reading your notice of Cratægus orientalis in your issue for December 25 last, especially as we have two very fine specimens here, which were planted between fifty and sixty years ago. It is unquestionably one of the most effective of the thorn family, but to ensure justice being done to it, the trees should be planted in an isolated position on the lawn as here. The flowers are beautifully scented, and during May, when the trees are in flower, and again in autumn, when covered with the fine showy fruit, they are most attractive, and always much admired by visitors. Another species, C. punctata, planted here at the same time, although much more robust in growth, and requires more room, is nevertheless worthy of being planted much more extensively than has yet been the case; it is more pendulous in habit of growth than the first named, and when covered with its large red fruit during autumn it forms an object of much interest.

Plant Transpiration.—For some time past Mr. Henry H. Dixon, of Trinity College, Dublin, has been endeavouring to decide whether the energy used in raising the water of the transpiration current is derived solely and directly from the inflow of heat at the evaporating surfaces of the leaf-cells, or whether stored energy (*i.e.*, vital force) is in any way responsible for work done. It has been observed that plants transpire into a space saturated with moisture. But Mr. Dixon states in *Nature* that he is not aware that it has been pointed out that this transpiration will continue when no light falls on the leaves. Without this precaution we cannot assume that the space is really saturated at the surface of the leaves; for they will convert some of the light into heat, and so lower the state of saturation at their surfaces. In his experiments small leafy branches were cut and set in a watery solution of eosin under a glass receiver. Beside the vessel containing the eosin, and under the receiver, a beaker filled with boiling water was placed. The receiver became immediately filled with water vapour, and, as the space was continually falling in temperature, owing to the cooling of the beaker, it remained always in a state of saturation. These arrangements were made in a feeble light, and then the receiver branch and all were set in total darkness. It is to be mentioned that a wet board cut off the direct radiation of the beaker from the branch. After an hour it was found that the eosin had risen into the leaves of the branch. In order to ensure that this rising was not due to reduced air pressure, previously obtaining in the water conduits of the branch, experiments were made in which any reduced pressure was equalised by setting the branch for one hour standing in water under the receiver, before setting it in eosin. The same result was obtained in these cases. The raising of the eosin in this experiment seems probably due to a pumping action in the cells of the leaf, depending upon vital processes taking place there. This surmise is confirmed by the fact that the elevation of the eosin does not take place in a saturated atmosphere if the leaves have been killed. This may be proved either by leaves killed by immersion in water at about 90 degrees C., or by exposure to chloroform vapour. If the pumping action be a "vital" process we would expect it to be dependent upon a supply of oxygen, like growth and grotropic curvatures, &c. Mr. Dixon, in fact, found this to be the case. Thus a branch wholly surrounded by water will draw up eosin from a vessel below, if exposed to light. The raising of the eosin will be but little if the light be cut off from the submerged branch. The action of light supplies the leaves with oxygen set free by assimilation; in the dark, however, the leaves can only obtain the small amount of oxygen dissolved in the water, and perhaps a little, too, derived by intramolecular respiration. With this limited supply the elevation of the eosin is inconspicuous. The oxidising processes taking place in the leaf-cells must bring about some minute rise in temperature. This will, of course, favour evaporation. But Mr. Dixon believes that this effect would be far too small to account for the whole phenomenon of transpiration into saturated spaces. That a very considerable amount of the pumping action is located in the leaves, may be shown by employing large leaves set upright in the eosin. It will be found that in a dark saturated space the veins of such large leaves severed from the stem will quickly become injected with the colouring fluid.

Diseased Hellebores.—Some badly diseased plants were received by the Scientific Committee of the Royal Horticultural Society from Mr. F. W. Burbidge, Trinity College Gardens. They were submitted to Kew for examination, and have been reported upon as follows: "Phoma effusa, Desm., is the name of the fungus attacking the hellebores. The diseased portions should be removed and burned, as at this season the fungus is producing myriads of spores, which live as saprophytes on humus in the soil for some time before they are capable of acting as parasites. The hellebore shoots of next year will be infected by these spores. The above alternation from a parasitic to a saprophytic mode of life enables the fungus possessing one form of fruit only, as in the present instance, to tide over the period during which its host plant is not actively growing. Spraying with a solution of potassium sulphide (one ounce to three gallons of water) when the leaves first appear next season would to some extent prevent the chances of inoculation from floating spores."

Forestry Essays.—The English Arboricultural Society offers medals for essays on the following subjects: (1) The planting, maintenance, and management of a plantation for the first twenty-five years, on (*a*) maiden land, (*b*) land previously planted; (2) The felling and barking of oak or larch timber, and the best modes of drying, housing and stacking, and preparing the bark for delivery to the tanneries; (3) The different methods adopted in the measurement of standing and felled timber, with diagrams, if possible; (4) Original observations on any diseases attacking forest trees not yet thoroughly investigated; (5) The destruction of the insects most injurious to forest trees not yet reported on, and coming under the notice of any individual member in England; (6) The results of any experiments having a practical bearing upon forestry; (7) The best method of reclaiming, draining, and replanting bog land, and the most suitable variety of trees to plant. The competition for the medals for the first two essays is limited to assistant foresters, but for the remaining essays the competition is open.

Select Cactus Dahlias.—Through the courtesy of Mr. J. F. Hudson, honorary secretary, we have received the select list of cactus dahlias for 1898 prepared by the National Dahlia Society. The varieties enumerated are Alfred Vasey, Annie Jones, Annie Turner, Arachne, Beatrice, Bertha Mawley, Britannia, Capstan, Chas. Woodbridge, Cinderella, Countess of Gosford, Cycle, Daffodil, Delicata, Earl of Pembroke, E. J. Deal, Fantasy, Fusitier, Gloriosa, Harmony, Harry Stredwick, Iona, Island Queen, J. E. Frewer, Juarezi, Keyne's White, Lady Penzance, Mary Hillier, Mary Service, Matchless, May Pictor, Miss A. Nightingale, Mrs. A. Beck, Mrs. A. Peart, Mrs. Barnes, Mrs. Gordon Sloane, Mrs. H. Cannell, Mrs. John Goddard, Mrs. Leopold Seymour, Mrs. Montefiore, Mrs. Wilson Noble, Night, Regulus, Robert Cannell, Starfish, Tillie, and Violet Morgan.

Useful Scale Insects.—The scale insects with which cultivators in the United Kingdom are familiar are so injurious to fruit trees and ornamental plants growing under artificial conditions that all the members of the group have come to be regarded as pests. This, however, is not the case, for, as pointed out by Dr. Howard, several possess considerable economical value. For many years the cochineal or cactus scale insect (*Coccus cacti*) was used as the basis of an important red dye, until superseded by the introduction of aniline dyes. In the same way the European Porphyrophora was used in the production of a purple dye. In addition to the dye insects, we have the Lac Insect (*Tachardia lacca*), which produces nearly all of the shell-lac, stick lac, and button lac of commerce. This species is Asiatic in its distribution; but in the south-west States of America, upon the very abundant creosote bush, a lac insect occurs in an enormous quantity, the commercial possibilities of which have not been developed. This is Tachardia larreæ, which has been known to science only since 1881, but was long prior to that time known to the Indians, who for many years have been in the habit of collecting the scale insects and forming them into more or less elastic balls, which their runners were in the habit of kicking before them as they journeyed from one point to another. Again, a pure white wax, secreted by the Chinese and Japanese *Ericerus pé-la* and by the Indian *Ceroplastus ceriferus* is of considerable commercial importance, and is much used in the Eastern countries, both in the making of wax candles and in medicine. The Chinese wax has high illuminating power, and resembles beeswax in its chemical composition. Dr. Howard also calls attention to the fact that in the far south-west of the United States there is a wax insect (*Cerococcus quercus*) which apparently needs careful investigation from the commercial point of view. Three species of oak are recorded as offering food for this insect, and Dr. Howard recently received specimens of the insect from California. They were not sent in position on the twigs, but had been compressed together into a more or less pliable lump, somewhat resembling a lump of india-rubber, but not possessing the same elasticity. The substance, it is remarked, makes an admirable chewing material, as it readily takes and long retains flavours.

Holly with Red and Yellow Berries.—Mr. C. Turner, Slough, sent some sprays of holly to R.H.S. Scientific Committee, on which he remarks, "They are cut from a large tree which retains its berries for two years. The berries are yellow in the first year, but change to red in the second year." As no seasonal break was distinguishable between the group of yellow and that of the red berries below it on the same stem, some doubt was expressed, and some further information desired. This Mr. Turner has kindly promised to furnish.

Public Gardens in Jamaica.—A history of the public gardens and plantations in Jamaica is contributed to the "Proceedings" of the Botanical Society of America by Mr. W. Fawcett, the director. From this we learn that the first botanic garden in Jamaica was formed about one hundred and fifty years ago by a private individual, Mr. Hinton East, on his property near the present village of Gordon Town, nine miles from Kingston. It was shortly afterwards taken over by the Government, and two gardens established. But it was only within about the last thirty years that a serious attempt was made, under Sir J. B. Grant, to make the gardens of economic value to the Colony, during which time much has been done to determine what foreign importations are most suitable to the climate. There are now six larger or smaller gardens, viz., The Parade, King's House, Hope, Hill, Castleton, and Bath Gardens, varying greatly in their climatal conditions. Mr. Fawcett estimates that the native flora of the island includes about four hundred and fifty ferns, and two thousand one hundred and eighty species of flowering plants.

From Mosses to Begonias.—It is interesting to note that Mr. John Laing, V.M.H., whose portrait was given in our recent plate of medallists, was the recipient of his first honour exactly fifty years ago. In 1845 the Royal Caledonian Society offered a silver medal, to be competed for in 1847, for the best collection of mosses indigenous to Scotland. Mr. Laing, then a promising young botanist, entered the lists, and from February to August, 1847, he carried on his investigations, confining his researches to within a ten-mile radius of Edinburgh, and gathered a remarkable collection, including many rare species. This complete collection Mr. J. Laing, sen., still preserves in its original form, bound in a thick demy octavo volume, and entitled "A Fasciculus of Mosses, collected in the vicinity of Edinburgh from February to August, 1847." The young botanist was awarded the coveted medal as a result of two years' painstaking and persistence. Mr. Laing recently confessed that although, acting under the influence of the repeated counsel of horticultural friends, he developed into a nurseryman, his "first love" was botany; notwithstanding which, however, his success in the wider field has fully justified the devotion of his maturer years.

Rats and Brussels Sprouts.—It is probable that the good folk of Langley Bucks, will petition for a local relaxation of the dog-muzzling order, so that their four-footed friends may assist in putting down the plague of rats. Green crops in many gardens have been eaten up entirely, and others partly. The station-master at Langley has lost a fine crop of Brussels sprouts, the buttons having been cleared by the rats as completely as if picked by hand.

Mistletoe and Holly have been sold in enormous quantities this season, together with other evergreens suitable for Christmas and New Year's decorations. The greater part of the mistletoe comes from Brittany, Cherbourg, and St. Malo; a considerable quantity coming from the Channel Islands, and a good supply of home-grown from Worcestershire and Gloucestershire. The holly that finds its way to Covent Garden comes chiefly from Sussex, Bedfordshire, and Surrey. Christmas trees, that cause so much enjoyment to the young, come from various centres; Belgium supplies enormous quantities, as does the Woking district of Surrey. In the North of England and Scotland the tops of pines large enough for timber are cut and distributed widely to supply the large demand for Christmas trees.

The Allotment Holders of Eynsford had a busy evening recently on the occasion of an exhibition of produce, the distribution of prizes, and the conclusion of a series of lectures on horticulture by Mr. W. P. Wright. Mr. Henry Cannell occupied the chair, and presided over an attendance of more than a hundred. Mr. Wright alluded to the admirable movement initiated by Sir Percival Hart-Dyke about seventy years ago in the terms of his first agreement with the allotment holders of Eynsford, viz., that the ground must be kept clean, regularly manured, and well tilled. The great interest of the evening was the presentation of a silver cup, given by Mr. H. M. Pollett, to Mr. William Howard, aged 81, who can probably show a longer tenure of an allotment than any other man in the kingdom. The cup records the jubilee period of sixty years, but Howard has held his allotment for sixty-six years, and has in it a fine Winter Quoining apple that he planted sixty years ago. Mr. H. Cannell, sen., in making the presentation, congratulated the recipient, and expressed a hope that so excellent an example would not be lost on those present. There was a first-rate exhibition of vegetables, fruit, including some of Howard's Winter Quoining apples, honey, and preserves from the hundred allotments Eynsford now possesses. Mr. Cannell distributed the prizes, and a pleasant gathering concluded with a vote of thanks to Mr. Wright, Mr. Pollett, Mr. Cannell, and to Mr. E. D. Till, the energetic local secretary of the technical education classes.

A New Spidery Chrysanthemum has been obtained by Messrs. H. Cannell and Sons, Swanley. It is a late-flowering and pure white sport from the elegant variety named Mrs. Filkins, and is an improvement upon the parent in size and substance. The tubular florets are much divided towards the apex, and thus the whole bloom is extremely graceful and unique, available alike for bouquets, wreaths, buttonholes, or table decoration during the Christmas season, for the flowers appeal not alone to lovers of the curious. The blooms sent us by Mr. H. Cannell reminded us of a particularly fine form of the pure white Sweet Sultan, and they certainly were as suitable in a cut state, with the advantage of being in season in December. We have every confidence that spidery chrysanthemums have a great future, and are sure that the white Mrs. Filkins will give the necessary impetus to their cultivation.

Flowers and Insects.—A short time since we directed attention to Professor Plateau's observations of the way in which flowers attract insects, from which he inferred that the presence or absence of brightly-coloured corollas possessed little or no influence on their insect visitors. These researches are now concluded, and he states that repeated experiments on seventeen species of plants, all anemophilous, prove that it is sufficient to place on the greenish or brownish inconspicuous flowers some artificial nectar, represented by honey, in order to attract numerous insects. Moreover, it appears from Professor Plateau's personal observations that insect visits, often frequent, have been observed on ninety-one forms of entomophilous plants having flowers devoid of conspicuous colour, viz., forty-one with green, thirty-eight with greenish, and twelve with brown or brownish flowers. The author has verified the coloration for seventy-two of these plants, and has himself observed the visits of insects to sixty-three, or more than two-thirds of them. Professor Plateau concludes that insects are little affected by the presence or absence of brilliantly-coloured floral organs; what they seek is the pollen or nectar, and in finding these their sense of vision is merely accessory; while, on the other hand, they are guided with certainty by some other sense, which can only be that of smell.

The Cultivation of the Strawberry was the subject of an instructive paper by Mr. H. Dunkin, read at the monthly meeting of the Birmingham Gardeners' Association. A brisk discussion followed the reading of the paper, and a hearty vote of thanks was accorded Mr. Dunkin and Mr. J. Hughes, who presided.

A Hybrid Blackberry is figured and described by an American contemporary under the name of the Mammoth Blackberry. It is said to be a hybrid between Rubus ursinus, the common wild Blackberry of California, and the Texas Early, a form of Rubus villosus, recently obtained by Judge J. H. Logan, of Santa Cruz, the originator of the Loganberry. The Mammoth, which is a cross between two plants, which produce medium-sized fruit, curiously bears berries of immense size, fruits two and three-eighths of an inch in length being common. The canes of the Mammoth are large and thickly covered with small short spines; starting early in March, they grow thick and stout until about five feet high, and then becoming pendulous or semiprostrate, grow from twenty-five to thirty feet more during the season; late in the autumn the tips of these shoots take root. Producing no adventitious root-buds, this variety cannot be propagated by root-cuttings, and the only way to multiply it is by means of stolons. The Mammoth begins to grow and flower early in the spring and ripens its fruit at Santa Cruz the last of May, or some weeks earlier than the Lawton. The flavour of the fruit is described as more acid than that of the Lawton, but when perfectly ripe is said to be sweet; when cooked or canned the flavour is identical with that of the fruit of the wild California Blackberry, which is excellent, although, owing to its poor bearing qualities, it is rarely cultivated.

A NEW YEAR'S GREETING.

WHEN my good friend the Editor, in his most insinuating tones, asked me if I would not write a message for the new year, I felt very much like the fly in the fable, who was wheedled by the flattering words of the spider to enter the pleasant house he had prepared for him, and I now feel like the same poor fly buzzing about not knowing what he is to do. I am, however, bound to say something, and I must be contented to bear all the scolding that may be heaped upon me and the Editor for taking up valuable space.

In looking back upon the past year, so memorable in the annals of our country, the first thought that strikes one is, How has horticulture fared in the Jubilee rejoicings? There were several attempts made to connect the two together, but somehow or other most of them fell flat; it would have been a grand notion to have carried out the idea of building a Jubilee Hall for Horticulture, as suggested in the pages of this journal; it was one environed with difficulties, and I think it must be admitted is a lasting disgrace to all those in the metropolis who are supposed to be deeply interested in horticulture that the opportunity offered a few years ago of securing a site for such a building was not seized upon, for this is the great difficulty which confronts all those who wish to see the idea carried out. There is, however, one exception to this failure, and that was the action of the Royal Horticultural Society in instituting, with the Queen's consent, the Royal Victorian Order of Merit for Horticulture. As it has been explained, the selection of the sixty recipients of the honour did not owe that position entirely to the action of the Council, horticulturists in all parts of the kingdom were invited to forward lists of those whom they considered most worthy, and it was relying on those lists and their own knowledge that the Council made the selection. Of course there are a number of virtuous people who are above all such petty distinctions, and who ridicule those who have gladly received the order; but, with all that, I believe as time rolls on the initials V.M.H. will be looked upon with more and more favour.

It is needless to enter into details upon the many subjects which the pursuit of horticulture brings before us, but there are a few which have particularly struck one during the past year; thus, for instance, there has been a marked increase in the taste for decorative gardening, and I think that there are dangers connected with it. The bedding-out system, which had so carried away people for many years, had grown more and more into disfavour, and deservedly so; it is still well adapted for public parks, but has been more and more abolished in private gardens, while at the same time on all hands it is said we want decorative flowers. Is it the narrow-mindedness of an old florist that makes me nervous when I see the extremes to which this is carried? Take for example two flowers in which I have ever been deeply interested, the carnation and the rose; with regard to the former the old florists' varieties are giving way in many a garden to what are called the border and fancy varieties, but it will be an evil day when the old bizarres and flakes, which used to rejoice us, have to give place to those of modern introduction. It is just possible that the over-dressing of the show flowers may have led somewhat to this; for it was often said, and I fear with some degree of truth, that no matter how well you might grow your flowers if either you or some one you employed could not dress them you stood but little chance of obtaining a prize. There was a good deal of truth in this, but I think the main reason for their supersession was the more showy character of the fancy varieties, which made them so much more conspicuous and effective in the garden than the older kinds. The same holds good with regard to the rose; there is a fashion for running down the old well-established favourites, calling them fat and over-fed, and I know not what, and we are exhorted to give more attention to the "dear old garden varieties." It may be all very well for those who have got tired of exhibiting, or have found themselves put into the background by successful competitors, to take up this cry; I am not dead to the beauty of many of these garden varieties, they are well adapted for large places where all varieties of the rose may be cultivated, but woe to the day when they supersede the exhibition kinds—when Charles Lefebvre and Marie Baumann, or Madame Gabriel Luizet are sneered at, and we are told we must grow instead Bardou Job, Gustave Regis, or Macrantha.

So again it is with the dahlia. It is the cactus varieties which now seem to find favour, which in former years would have been discarded as ill-formed, and the beautifully-modelled old flowers are now to be relegated to a back seat; we are a people fond of extremes. Some years ago we ran after single dahlias, but these have been pushed on one side, and now we are on a different track. Well, it is all good for trade, and so we must look for a change by and by. There is another point which the past year has brought prominently forward, and has occasioned, and justly so, strong animadversions, the excessive multiplication of awards for these flowers. When I see that between sixty and seventy honours are given to the chrysanthemum and between forty and fifty to the dahlia we must be sure there is something wrong. The former flower honours were given to those of a wishy-washy colour; and one may well ask, Can these be distinct, and can anyone hope to keep up with such an outrageous number? Of course chrysanthemum growers feel that there are too many new varieties honoured, but there seems to be a sort of moral fibre wanting to stem this torrent.

I do not think that there are any symptoms of an abatement in the love for flowers amongst us; quite the contrary, it seems to be increasing every day, and the difficulty now is to keep pace with the demand. Everywhere they are to be met with; they brighten up our wedding festivities and our dinner tables; we use them to signify our tokens of respect for those who are gone, although I cannot but feel that this is overdone, for when one reads that at the funeral which took place the other day, of the late Mr. Terris, whose tragic death attracted such general sympathy, six vehicles were required to carry the wreaths and other decorations which had been sent in, we may well ask, Is not this going too far?

It is somewhat curious to note how fashion changes with regard to flowers. Many years ago a well-known London nurseryman asked me, "What flowers shall we go in for now?" and then added, "I think I shall take up the tuberous-rooted begonia," and we know what marvellous results were attained; but now they have reached such a state of perfection that very few persons think of growing the named varieties, as nearly as good are to be obtained from mixed seed. The dwarf-flowered cannas have lately been much exhibited, and unquestionably these are very ornamental and useful. Good results have already been obtained by the hybridiser, and knowing what good things have resulted in other flowers we may hope to see still more brilliant results, not only are they useful for the garden in autumn, but they are eminently suitable for pot culture. The taste for herbaceous and Alpine plants shows no sign of diminution, and although no very remarkable new species have been introduced of late, yet more knowledge as to treating those we have has been acquired, and many who have had to deplore failure can now speak of success. Probably the most striking of herbaceous plants of late years have been the eremuri and ostroskia, and we are continually hearing of the successful cultivation of both of these, large numbers being annually raised from seed. Orchids still hold the palm amongst stove and greenhouse plants, and when one sees the number of lælias, cattleyas, and cypripediums which are yearly honoured with decorations the question comes home whether the complaint that there are too many of these awards is not correct, just as in the case of the more plebeian chrysanthemum and dahlia.

The closing days of the year bring with them many a sad and painful memory, and it is one of the sorrows of old age that we have to look back and see what vacancies time has made. During the past year several well-known horticulturists have passed away, many of them at a ripe old age, others prematurely cut off. Of the former two stand prominently out—Dr. Robert Hogg, for many years editor of the *Journal of Horticulture*, and author of the standard work on fruit, "The Fruit Manual." He was so constant an attendant at the meetings at the Drill Hall that he has been much missed, for his wide and extensive knowledge was ever available in the deliberations of the Fruit Committee; it is a pleasant thing to think that his memory will be kept alive in the quarter where he would have most wished; friends have had a die cast for a Robert Hogg memorial medal, which will be given to the Royal Horticultural Society, who will from time to time award the medal for successful exhibits in fruit. The other was Mr. James Bateman, at one time, in the early days of orchid growing, the most successful cultivator, and whose beautiful place at Biddulph Grange afforded one of the best examples of tasteful and successful horticulture in the kingdom. Colonel Trevor Clarke was another well-known character. He was fond of scientific horticulture, and was the author of many experiments, which he carried out with great skill. Mr. Head, the garden superintendent at the Crystal Palace, succumbed after a long and most painful illness, which had drawn out the sympathy of those who had been wont to admire his energetic management of the various horticultural exhibitions at the Crystal Palace. Two clergymen who did good work in their respective spheres, I mean as far as horticulture is concerned, were the Rev. Charles Fellowes, of Shottesham Rectory, near Norwich, to whom we owe many beautiful varieties of picotees and show dahlias; and the Rev. E. N. Pochin, of Barkby Vicarage, near Leicester, who was at one time one of our most successful rose exhibitors and one of the best judges I ever knew. We are sometimes inclined to question whether in this, as in other walks of human life, adequate successors can be found; we speak of our losses as irreparable, but they are not really so. A great statesman dies or passes out of public life and we are inclined to think the world cannot go on without him; but somehow or other it does, and after a while we become reconciled to the loss; and so in art and science we lose one and another honoured name, but we find their place supplied by those of whom we had thought but little.

Now, let me add one word of exhortation. We have no need of commendation of Francis Bacon, who dilates so well on the pleasures connected with the garden; we cannot have followed our favourite pursuit without ourselves being able to bear testimony to the happiness and pleasure which it has afforded us. Surely it is a pleasant thing to be able to look round continually upon the beauties with which God, our Father in heaven, has endowed our earth, to see in the lowliest flower as well as in the loftiest tree proofs of His handy work. We are sometimes pitied by the town dweller because he thinks our life must be so dull and monotonous; I do not think it can be so where there is a love of Nature in the heart, and when we look out, through the things which surround us, up to Him who is the Maker alike of us and them. And so, my friends, let the words of an old man encourage you to go on; cultivate your flowers with as much energy and intelligence as you can, but ever remember that they are evanescent, and strive to look up to Him who ever used the things around Him, the lily and the corn, to teach the solemn lessons of His holy religion, so that at the last, when your time comes, you may be amongst those who shall be gathered into the eternal kingdom, where, midst the never-withering flowers of the heavenly paradise, you may learn more and more of the power and goodness of Him who calls His people out of darkness into His marvellous light. H. H. D.

Greasebanding Apple Trees.—I am deeply concerned for Mr. H. Clarke's disappointment in not catching any winter moths on his greasebands, but am again solaced by the reflection that probably he has none infesting his trees to catch. It does not at all follow that because there are apple trees there are moths also. There may be or may not be. If there are, and the greasebands are properly secured to the stems of the trees early in the autumn, most of the female moths certainly will be caught. It the grease sets, paint it over occasionally with oil of practically any description, though linseed oil is as good as any. Of course the bands should be secured very tightly to the stems, and prior to doing so, it is well to scrape and scrub the stems so that the paper bands are fixed tight to the stems.—A. D.

THE NATIONAL HORTICULTURAL SCHOOL OF VERSAILLES.

THIS school was founded on December 16, 1873, and inaugurated December 1, 1874. It consists of the Palace Gardens, representing a total area of twenty-five acres, created by La Quintinie in 1683. The object of the school is to form competent and educated gardeners, possessing the necessary theoretical and practical knowledge bearing on the art of horticulture. While Le Nôtre laid out the park and grounds of the palace, the creation of the fruit, flower, and kitchen gardens is the work of La Quintinie. He had to make a Dismal Swamp blossom like a rose. That marsh was the receptacle for all the water that trickled down from the neighbouring hills. In winter it was mud, in summer baked brick. He commenced operations in 1678, completed them in 1683, at a cost of 1,800,000 francs. La Quintinie was a singular man. He was a barrister, but never pleaded; a theologian, but never preached; and a passionate horticulturist and agriculturist, full of original ideas. He travelled a good deal; he visited England twice, and James II., who had a great esteem for him, tried to retain his services, but La Quintinie preferred the offers of his own king Louis XIV. He assured the latter he would supply the royal table with new asparagus and sorrel in the month of December; radishes, lettuces, and mushrooms in January; cauliflowers in March; strawberries early in April; peas in May; and melons in June. And he more than kept his word.

Visitors to the Palace of Versailles have doubtless remarked the sheet of water familiarly known as La Pièce des Suisses—so called because the excavation, twelve feet deep, was effected by a regiment of Swiss soldiers. Parallel with this was the marsh site of the gardens. It was filled up with the excavated earth, or rather sand; over the latter was spread layers of loamy soil transported from the neighbourhood of the Sartory hills. Then an aqueduct was constructed underneath, into which the drains emptied. That became also the water supply for the gardens. The herculean task accomplished, La Quintinie, who had given the area a general slope, divided it into thirty gardens, enclosing the centre with dividing walls running in different directions to secure shelter and to accommodate fruit trees. The plan of the garden to-day is not radically different from the original; it is a series of parallelograms, with wall spaces, espaliers, hothouses, conservatories, beds, glasses, and "forceries" in general. There is a total glass surface of 6,700 square yards. All the forcing houses are heated with hot-water pipes, and the temperate conservatories, melon frames, &c., are concentrated on the left of the entrance of the grounds. This secures economy and methodic supervision. The entrance to the establishment is by the Rue du Potager. The mansion had Mansard for architect. The contiguous buildings are the offices and lecture-rooms—the latter once the orangery, so there is plenty of air and light; the museum, with its collection of eight hundred fruits, moulded and coloured after Nature, classified according to varieties, and into three qualities. Proceeding towards the centre of the garden, through parterres of flowers and rows of ornamental shrubs, the *bassin*, or pond, eighty-five yards in diameter, is reached, and wherein aquatic plants are arranged. At the head of one of the two flights of stone steps is the bronze statue of La Quintinie, holding a branch in his left hand, and surveying his work. His true monument is "Circumspice."

The culture of fruits, vegetables, flowers, shrubs, &c., is divided into two groups, that in the open air and the other under glass. The linked parallelogram gardens are devoted and divisioned each to a special culture and to corresponding best varieties of the trees and plants. There is a winter and a botanic garden, also a very important nursery, which plays an invaluable rôle in the curriculum of studies. There are 15,684 fruit trees of all kinds and varieties, 5,500 yards of espaliers, and 14,000 square yards of wall space for fruit growing. The importance of the culture generally must be judged from type samples. Thus, there are 5,171 pear trees, embracing 557 varieties; 8,566 apple trees, comprising 309 varieties; 383 peaches, and 94 varieties; 915 vines, representing 61 varieties; 190 cherry trees, of 16 varieties; and 107 plum trees comprising 25 varieties, &c. These do not include orange, olive, pomegranate, almond, walnut, &c., trees. The forms of the trees are those of ordinary or fantastic training, vertical, horizontal, oblique, in single or superposed rows, palmette, goblet, candelabra, pyramid cones, &c. In the forcing houses, the Frankenthal, Foster's White Seedling, Black Alicante, Gradiska, Bondalès, &c., are the leading grapes; in peaches, thirty varieties, figure the Mignonnes, Belle Beausse, Amsden, and Cumberland; among cherries, the English varieties are preferred, not omitting the Empress Eugénie; for plums, the Victoria and Washington. There are under glass the following trees: Two hundred and sixty-five cherry, 356 peach, 568 vines, 166 plums, 63 figs, as well as gooseberries, raspberries, &c. There are 500 melon frames and 1,000 more for raising vegetables. One variety of forced strawberry predominates, Docteur Morère; 10,000 pots are annually devoted to its culture. Four "houses" are devoted to pine apples of several varieties. Some of the fruits weigh nine pounds. It was in this garden that the first pineapples were raised, in 1733, in France.

The vegetables proper, some three hundred species and varieties, excluding the "forceries," are raised in measured sub-divisions of some of the thirty quarters, and separated by espalier borderings. The watering is effected by means of reservoirs situated in the corner of a square, and fed from the subterranean aqueduct; water cans and hose-sprayers do the rest. In the squares allocated to fruit trees, the soil displays no signs of exhaustion from the same species of tree succeeding during two hundred and fourteen years; the fruits are sound, and the yield heavy. When an old tree is condemned, the roots are thoroughly extirpated, and fertilisers added to the soil. The large cellars serve for mushroom raising, and the blanching of seakale, winter salads, &c.

Respecting floriculture, it is fully taught from culture in the open air, in the temperate conservatories, and the hot houses. Every important flower or ornamental shrub is represented; in roses there are five hundred varieties. *Ab uno disce omnes.* Special attention is given to orchids. The produce of the garden is sold to the public for cash, and Versailles, though it no longer possesses the light of other days, has a large and wealthy population, especially of rich foreigners, who, world-weary, or world-wounded, come there to rest, and to die.

The instruction given at the National Horticultural School of Versailles is gratuitous; the number of pupils is limited to one hundred and twenty, of whom forty retire annually, after completing their three years of study. Candidates must not be less than sixteen, and not more than twenty years of age on entering the garden, save in case of military service, when it is extended to twenty-three years. The pupils wholly work the establishment; they arrive at five o'clock in the morning in summer, and at six in winter, and remain till nine in the evening; they knock off work twice in the day for an hour and a half each for meals. They are not entitled to any vacation, but can expect a fortnight in town about August and September. Candidates must submit to an entrance examination if they have not school certificates of efficiency. Before entering a superior grade of studies the pupils are annually examined; those with a bad record of progress must leave. At the end of the third year the pass examination takes place; if satisfactory a diploma is given, signed by the Minister of Agriculture. There are six annual scholarships of 1,000 fr. each open to competition, independent of two prizes of 1,200 fr. to be awarded to the best pupils on completing their third year. The latter sum is to enable them to complete their studies in a foreign horticultural school or a leading horticultural establishment in France or elsewhere. Pupils must support themselves, but several horticultural societies, farming syndicates, learned associations, municipal councils, &c., pay the expenses for a young man of promise. The present Director-Professor of the school is M. Nanot, who succeeded the late and original director. M. Hardy, a gentleman, as his name indicates, of English extraction, and of unquestionable ability. There are also nine professors for the chief departments of horticulture, floriculture, ornamental gardening, and instruction is given in chemistry, geology, &c., as well as in book-keeping, levelling, drawing, and geometry. There are two chief gardeners and two assistants. The pupils under the head gardener visit the most important garden and horticultural establishments in the vicinity of Paris, and each pupil must make a report on his visit. The school is well provided with up-to-date educational apparatus; the walls are well hung with object lessons, and the museum is rich in specimens. In winter four, and in summer two and a-half hours daily are given to study, plus three hours to lectures and examinations, so that from five to eight hours represent the time devoted to out-door manual labour. Instruction is given in the workshops—how to repair the *matériel*, in carpentry, glazing, painting, printing labels, &c. The pupils follow fifteen distinct courses of lectures by the professional staff. For out-door instruction they are divided into five squads of twenty-four pupils each, and devote a fortnight in rotation to learning forcing, arboriculture, and fruit growing, floriculture in open-air, culture under glass, and the ordinary raising of vegetables. On quitting a section every pupil has to make a report upon the operations he witnessed and helped to execute. Since its opening in December, 1874, eight hundred pupils have graduated in the school. The establishment costs the State 90,000 francs a year, of which 30,000 francs are expended in providing the teaching staff, and the rest for working expenses. No account is published of the receipts for sale of produce; but that is not of vital importance, as institutions of an educational character can not be expected to be self-supporting. EDWARD CONNER.

VEGETABLES FOR EXHIBITION.

Knol-Kohl, or Kohl-Rabi.

KOHL RABI (*Brassica oleracea caulo-rapa*) is more generally grown on the farm than in the garden, as it makes an excellent food for cattle. At the same time, a small quantity should be grown in all large gardens, as in a young state it makes an agreeable change as a vegetable. It is quite hardy, and thus valuable in severe weather, and very little trouble is required to bring it to perfection. The seed should be sown at the same time as the principal batch of the brassica tribe, and transplanted as soon as large enough in rows two feet six inches apart, allowing two feet between the plants in trenched, heavily-manured ground. The hoe should be kept constantly employed about the plants to encourage quick growth, and in dry weather the crop should be kept well watered, and occasionally given good soakings of liquid farmyard manure. No other attention is required to mature the crop, which may stand and be drawn upon as desired. A small quantity of Early White Vienna for summer use and Early Purple for winter should be grown.

For horticultural exhibitions, Kohl Rabi is of little use, but at the cattle shows during the autumn it often forms quite a feature, and is most attractive to the general public. In an unlimited ornamental collection of vegetables both kinds should be included, more for increasing the number of kinds and adding to the effect than for their value. The roots should be thoroughly washed and left on, and most of the leaves round the bulb carefully trimmed off, leaving only the top fresh ones; nine to twelve examples should be the number staged.

Aldenham House, Elstree, Herts. E. BECKETT.

SOME GOOD WHITE ROSES.

IF I were asked to name what had proved the best dozen white roses in our rose gardens, they would be as follows: Boule de Neige, Merveille de Lyon Souvenir de S. A. Prince, The Bride, Niphetos, Madame Plantier, Coquette des Blanches, Madame François Pittet, Innocente Pirola, Edith Gifford, Madame Alfred de Rougemont, and Blanche Moreau (Moss). The first six have proved most useful and reliable. We also have several roses with a pale-blush tint of rather too pronounced a character to justify their being included among whites, but which may well be mentioned in connection with this article; such as Augustine Guinoisseau, Margaret Dickson, Souvenir de la Malmaison, Vicountess Folkestone, Mrs. Paul, and White Lady. Then we have a splendid acquisition in Bladud among pale flesh-coloured whites; also a grand pure white in Purity, both of which were introduced by Messrs. Cooling and Sons, of Bath.

Niphetos, sent out as long ago as 1844, is still the best pure white. Under glass we have no rose to compare with it. Every bud is long and of perfect form, while it opens into a really grand flower. There is no freer or more constant bloomer than this, and, with Perle des Jardins, it is probably the most generally grown rose for cut blooms. It is by no means so tender as many imagine, and we often obtain really grand blooms from the open. The northern show of the N.R.S. at Norwich, last July, contained one of the grandest flowers we have ever seen, and the silver medal was well deserved. In every way this was a typical bloom, as was amply proved by its beating the whole of the teas and noisettes among the nurserymen's classes. A warm season, a sheltered position, and, if not upon a wall, grown as a short standard, suits this grand old rose well.

Souvenir de S. A. Prince is comparatively new, having been sent out in 1889. This was a sport from another very old favourite, Souvenir d'un Ami, a rose that has held its own for more than half a century, being sent out in 1846, or two years after Niphetos. Souvenir de S. A. Prince is synonymous with The Queen, a sport originating from the same variety. It is a globular flower, opens well, is of the purest white when fully expanded, a good grower, hardy, and a very free bloomer. All of the grand characteristics of Souvenir d'un Ami are retained by this rose, the sole difference being in colour. It is the sweetest scented of all the pure whites.

Boule de Neige has been in general culture for thirty years. This is a hybrid noisette; and is a good grower, very hardy, a most perpetual bloomer, and one which lasts well both upon the plant and cut. When young there is a slight tinge of pale carmine rose upon the outside petals, but the whole is pure white when fully expanded. It can scarcely be put to the wrong use, and is sure to please.

The Bride, like Souvenir de S. A. Prince, is a sport from one of our most beautiful and valuable pink teas, viz., Catherine Mermet; a rose which has given us many grand sports, among which are Muriel Grahame, Waban, Bridesmaid, and the one now more particularly under notice. All rosarians know of the good qualities of Catherine Mermet and I need say no more than that The Bride is a counterpart of that old favourite (1867) except in being a pale lemon-white when young, and changing to pure white as it expands.

Merveille de Lyon is another grand grower. Its habit is a little more compact than Baroness Rothschild, while the foliage and bold way in which the flowers are carried are much like our old friend Baroness Rothschild, which has been our best pink for thirty years, notwithstanding its entire lack of perfume, a fault which must, unfortunately, be accorded to Merveille de Lyon as well. This is a large and massive flower, one of the best to open, and not spoilt by showery weather; indeed, like the Baroness, it seems to enjoy showers and dull weather.

Madame Plantier is a very old rose, and is one of the few varieties that were grown previous to the Queen's accession to the throne, and is still a favourite. It is of the purest white, a rather small-flowered hybrid noisette; a good grower, exceedingly free blooming, and a grand rose for standards, pillars, or massing.

Coquette des Blanches may be used in the same connection as the last named. It is hardier, and the flowers are rather larger, and of more globular form, but by no means so prettily shaped as Madame Plantier.

Madame François Pittet is a short and compact grower, very free, small, double, and with the exception of a carmine tinge in the younger stages during a hot summer, is pure white. This is a grand rose for bedding.

Innocente Pirola can hardly be called white. It is a creamy white, and, when young, has a faint tinge of pale salmon-yellow in the centre. As it ages, this is lost, and it approaches the whites nearer and nearer. It is a good grower and bloomer, rather tender, and every bloom, small or large, comes of perfect form with a high pointed centre. From a small bud this rose develops into a large and massive flower.

Hon. Edith Gifford, like the above, is a creamy white, and has a distinct flush of pale flesh in the centre when young. A very hardy rose this, one that may be depended upon in every way, but, unfortunately, rather more subject to mildew than others. Innocente Pirola also has this fault.

Madame Alfred de Rougemont is not much grown now, but it is one of our hardiest whites of medium size. A faint flush of pink is found upon the edges. Like many others in this selected dozen, it is an old favourite, being sent out in 1863.

Blanche Moreau is the very best white moss-rose we have. The flowers are large, beautifully mossed or crested, of the purest white, produced very freely in clusters, while the growth is vigorous. Our twelve would not be complete without this.

A few other whites are The Pet, Anne Marie de Montravel and Ma Paquerette from the miniature polyanthas; also the following three singles, Paul's Single White, Rosa multiflora or Polyantha simplex, and Polyantha grandiflora. Then we have the pure white Japanese, or Rugosa alba, and its semi-double form in Madame Georges Bruant; Aimée Vibert, a grand climber; Ducher, among the Chinas; also White Baroness, Mabel Morrison and Madame Lacharme. Turning to those with a flush of pale flesh, I would strongly recommend—

Viscountess Folkestone.—We have no sweeter-scented rose than this grand hybrid tea, nor a better grower and freer bloomer.

Augustine Guinoisseau is a compact and free grower, sweetly scented, and from early till late is never out of bloom.

Margaret Dickson gives us tremendous growth, which, if pegged down, will flower throughout its entire length, and produces grand flowers.

Mrs. Paul, a grand departure in Bourbons, from Cheshunt, is also a very strong grower that does best as a cutback when not too hardly pruned. This is one of our most distinct roses, large, of imbricated form, and much resembling a camellia in shape.

Souvenir de la Malmaison is too well known to need any comment.

Bladud is a new hybrid perpetual from Bath. This is a very large and well-formed flower, a much better grower than Madlle. Bonnaire, and with the same charming silvery white with a tinge of pale blush in the centre. This is a grand rose so far as we have seen it at present.

Purity is likely to be one of our very best pillar roses. The flowers are produced very freely throughout the whole length of the plant, and are of perfect globular form, with a prettily quilled centre, of rather more than medium size when fully expanded, and certain to become a most popular variety. When staged at the National Rose Society's Portsmouth exhibition in June 1897, by the introducers, Messrs. G. Cooling and Son, Bath, it attracted much attention, and is evidently destined to become a grand garden rose.

Those we have found to be the best half-dozen for pot culture from the above are, Niphetos, The Bride, Bladud, Edith Gifford, Souvenir de S. A. Prince, and Augustine Guinoisseau. As a white climber under glass, the climbing form of Niphetos is far ahead of all others.

A. PIPER.

CHRYSANTHEMUMS FOR 1898.

WITH the article from the pen of Mr. W. H. Lees, on page 808 of last year's volume, very few will disagree; still, in the list of varieties I think there is some room for improvement. Mr. Lees gives a list of fifty of the best Japanese selected from the older sorts, and from these, a further selection of the best twenty-four which are distinguished by an *; of course, the writer has placed the varieties in the position according to his own experience, which must be somewhat extensive. At the same time, to select the "best" twenty-four or fifty, is a task I, or few others, will attempt, for varieties good this year, may be almost failures next, a great deal depending on the season, and frequently the mode of stimulating.

Mr. Lees, in his selection of twenty-four, includes nine which may fairly be claimed as whites, and whilst admitting this class is the most extensive, many will agree with me that the percentage is too great. Pride of Madford, we are assured, has been consistently good, then why not include it, as I think it should be, in the first twenty-four, taking the place of one of the white varieties? Out of the fifty, no less than twenty-six may be termed whites or yellows; that these should preponderate to this extent many will question.

One variety which Mr. Lees notices—Madame Ad. Moulin—is certainly not required in the face of so many which are in every respect superior. It has been in cultivation several years but makes no headway. To include this among the best fifty and exclude Louise, Mons. Hoste, Mons. Andre, Pride of Exmouth, Mrs. C. Blick, Madame Gustave Henry, V. R. de Chezelles, Milano, Madame Ad. Chatin and some others, must be an oversight.

Many, if not all, of these last-mentioned varieties are superior, with most growers, to Mdlle. Thérèse Rey, Lady Saunders, and Sunflower. Mr. Lees does not place Sunstone and Mrs. F. A. Bevan among the first twenty-four. This, I think, is a mistake, as the first named has in many collections been very fine this season; a bloom in a non-competitive trade collection at the November exhibition of the N.C.S., was considered by some growers to be superior to the bloom of Mrs. Mease, to which the special prize as premier bloom was awarded. It is very distinct, both in colour and form, of great depth and substance. It requires an early start, stopping in April, and the early crown bud to be retained. Personally, I shall place it among the first six. Mrs. F. A. Bevan will also take a very high place when its culture is understood. It is also very distinct both in form and colour; on the early bud it is useless, but stopped early in April retaining the crown bud about August 20, is a method which seems to suit it. It requires good culture.

Mr. Lees places among the older varieties yellow Madame Carnot (whether this refers to G. J. Warren or Mrs. Mease it is not very plain), Western King, John Neville, Mrs. F. A. Bevan, Mrs. S. C. Probin, Mrs. G. W. Palmer, and Snowdon, all of which were sent out last spring, whilst others sent out at the same time come under the heading of "new ones," and in this latter class we find Madame Philip Rivoire, which was shown in the autumn of '95, whilst C. E. Jeffcock was catalogued in the spring of that season. Among the best of last season's novelties I would place Ella Curtis—a magnificent variety—Lady Hanham, Julia Scaramanga, Mrs. Maling Grant, Elthorne Beauty, Dr. Liebert, Geo. Seward, and Joseph Brookes; these, I have every reason to believe, will excel many of those mentioned on page 808. Master H. Tucker should also be placed among the best twelve of last season's introduction. Of the incurved varieties I say but little, except that I certainly should include Topaze Orientale among the best introductions of the season.

Exmouth. W. J. GODFREY.

PEACHES INDOORS AND OUT.

ONE of the first questions which will arise is this: Must the trees be grown indoors or out? Indoors by all means, if a suitable house is possessed, but outdoors if there is no structure available in which the conditions to be mentioned can be provided. To begin with, we want a house that is both light and well ventilated. A conservatory which has to be adapted to the wants of a mixed collection of plants is not suitable, nor is a span-roofed house with central and side stages for plants. The most suitable structure is a lean-to, not too sharply pitched, for in such a place the trees can be planted near the front, and their framework of shoots trained to a trellis under the glass, while tall "rider" trees can be grown against the back wall. Where there is no convenience at all for growing them under glass, they may be tried out of doors. Peach growing out of doors is not practised so extensively as it was, but good crops are still secured in some gardens. There should be a coping a foot wide fixed to the wall at the top, and this, with protection for the blossom in spring, will do much towards securing a crop.

Planting.

Planting may be performed from the time the leaves fall in the autumn until the following April. Those who are going to grow them out of doors should defer planting until February, so as to miss the severest part of the winter; by the following one they will be well established. A sound fertile loam, such as would grow good potatos, will be suitable, but peaches can do with a stronger soil than the noble tuber, if it is well drained and friable. They cannot be relied upon to give satisfaction, in a cold, heavy, adhesive clay. Where the soil is of this description drainage and the addition of large quantities of gritty matter will be needed before it will be in a suitable condition for the trees. Do not incorporate large quantities of rich manure, for it will only encourage gross, sappy, fruitless shoots. Mortar rubbish and wood ashes will make better additions than manure. In planting the trees take great care to have the soil firm. The firmer it is, short of being absolutely hard, the better, for loose soil encourages soft growth, and only firm, well-matured shoots will give heavy crops of fine peaches.

Training.

The best form of tree is the fan, so called from the shoots spreading out diagonally, and so forming an outline very much resembling that of a fan. There is no leader or upright growth, as in most other trained fruit trees. The amount of early training required will depend upon the age of the trees when bought. A two-year-old is the best cheap tree, because the framework has already been laid in the nursery, and a little observation will suffice to make the system which has been followed, and which should be continued, clear. It will be seen that the leader has been shortened, and that shoots radiate from the main stem below the point of pruning. All the back and front buds have been removed, and this should always be practised so as to have the side shoots on the top and bottom of the branches, never sticking out at right angles to the framework, for then they cannot be trained in to the wall. If the branches radiating from the main stem have not been shortened, cut them back to half their length, then the resulting growths will be strong, and a good foundation laid on which to build up a good fruiting structure.

How to Prune.

This follows naturally on the training, and is, indeed, a part of it. Peaches and nectarines bear their fruit chiefly on wood a year old, that is to say, shoots made one season bear the next. This being the case, the object is to have a regular succession year after year, a bearing shoot being always accompanied by a young one to take its place the following year. To begin at the beginning, having laid the framework of the tree in the manner just indicated, train in some young shoots, having them such a distance apart that the leaves will not be crowding and overlapping each other, but each with full exposure to the light. These will lose their leaves in winter, and in spring will break afresh. Blossoms will expand on them, and shoots will begin to push. Remove all these budding shoots gradually, except one near the base and another near the tip. The former is to be the bearing shoot of next year, and the latter is to draw the sap to the fruit. Let the young basal shoot develop healthily, and when the fruit has been gathered it will be ready to take the place of the bearing shoot, which may then be cut out. That is the system to follow season after season. Very strong, coarse successional shoots are not wanted. In fact, if they run to two feet long or more, and are very thick, lift the tree and replant it, so as to impart a check.

A Selection of Varieties.

The varieties, both of peaches and nectarines, are very numerous, and care must be taken in choosing them, so as to avoid sorts which all ripen together. The following peaches succeed each other, and are excellent varieties: Alexander, Hale's Early, Stirling Castle, Grosse Mignonne, Walburton Admirable, and Gladstone. Six very good nectarines, ripening in the order of their names, are Advance, Lord Napier, Elruge, Humboldt, Pine Apple, and Victoria.

The Black Fly.

This does terrible injury to many trees, establishing itself in the tips of the growing shoots, and crippling them so badly that they often do not recover all the season. Keep a sharp look-out for this pest in spring, and directly one is seen put some tobacco water in a bowl or basin, or make a solution by soaking a quarter of a pound of quassia chips overnight in a gallon of water, and adding four ounces of soft soap, then dip the infested shoots in the vessel.

A KENTISH GARDENER.

NEPHROLEPIS.

THE members of this genus are nearly all natives of tropical regions, though this does not make them any the less useful, for it is surprising the low temperature they will withstand, and even thrive in, under cultivation. They thus form some of the most useful of ferns for domestic decorations. All are of easy culture, and may be very readily propagated in several ways, either by spores—which is, of course, the most prolific method—or by the young plants which are very freely produced upon the thin wiry rhizomes that run so freely from all sides of old specimens. Another mode of propagation in some species is by the fleshy tuberous roots, that are also produced in quantity along the rhizomes of some species, and these, if detached and planted, soon form sturdy young plants. All the species enjoy a rich compost of a loamy nature, with the addition of plenty of leaf-soil and sand if the loam is inclined to be at all clay-like; and it is important to bear in mind to always give good drainage, as they all revel in an abundance of water at almost all seasons of the year.

For indoor decoration it is advisable to have a few young plants coming on to take the place of older specimens which are apt to become crowded, their crowns becoming raised above the soil, and thus preventing a vigorous growth. If this condition of the plants is allowed, they are more liable to become dry, and this is soon made evident by the casting of their pinnæ, and thus becoming entirely disfigured and useless. The number of species in cultivation is small, but they are all worthy of a place in collections of useful ferns. Several are extremely useful for planting out in rockeries, where they should be placed in an elevated position where the long drooping fronds are allowed room to develop to perfection. Among the best for this purpose is N. cordifolia v. tuberosa, the fronds growing several feet in length, and forming a beautiful covering to rocks. N. acuta is also useful in this way, as it is also for basket work, when, if planted in lasting material, it will last for several years without renewal. N. cordifolia has several varieties of great value for pot plants, N. compacta being one of the most generally seen plants of the genus, grown as it is in large quantities for market purposes. N. c. pectinata and N. c. phillipinensis are of a compact habit, and sturdy small specimens are always admired.

For exhibition or large specimens. the Japanese species N. davallioides and its variety furcans are both desirable, large and handsome plants being easily and quickly obtainable. This species was introduced into this country by the Messrs. Rollisson in 1852; the fronds are pendent and of a graceful nature, of a green glabrous nature, growing about three feet in length. The variety has the advantage of its pinnæ being crested and the apices being also deeply crested, thus forming a most striking object. Another large growing kind is N. rufescens var. tripinnatifida, which is distinctly a tropical fern, requiring a moist, hot condition of temperature. To grow this well it is best to start with young plants in spring, and to keep them growing by giving occasional shifts, and also preventing any attacks of thrips, which quickly disfigure this handsome species. It is erect in habit, with fronds, sometimes four feet long, of a pleasing light green colour. N. pluma, a Madagascar species, is of a very light elegant habit, especially suited for baskets, deciduous during winter. It possesses narrowish pale-green fronds, and requires to be rested in a good temperature, and never allowed to become thoroughly dry at the roots. A well-known form is N. exaltata, a plant common in the tropics everywhere, and introduced in 1793 to Kew. The fronds are slender, glabrous, and the pinnæ with serrated margins. N. exaltata v. hirsutata is less well known, and is known by its fronds being covered by ferruginous scales.

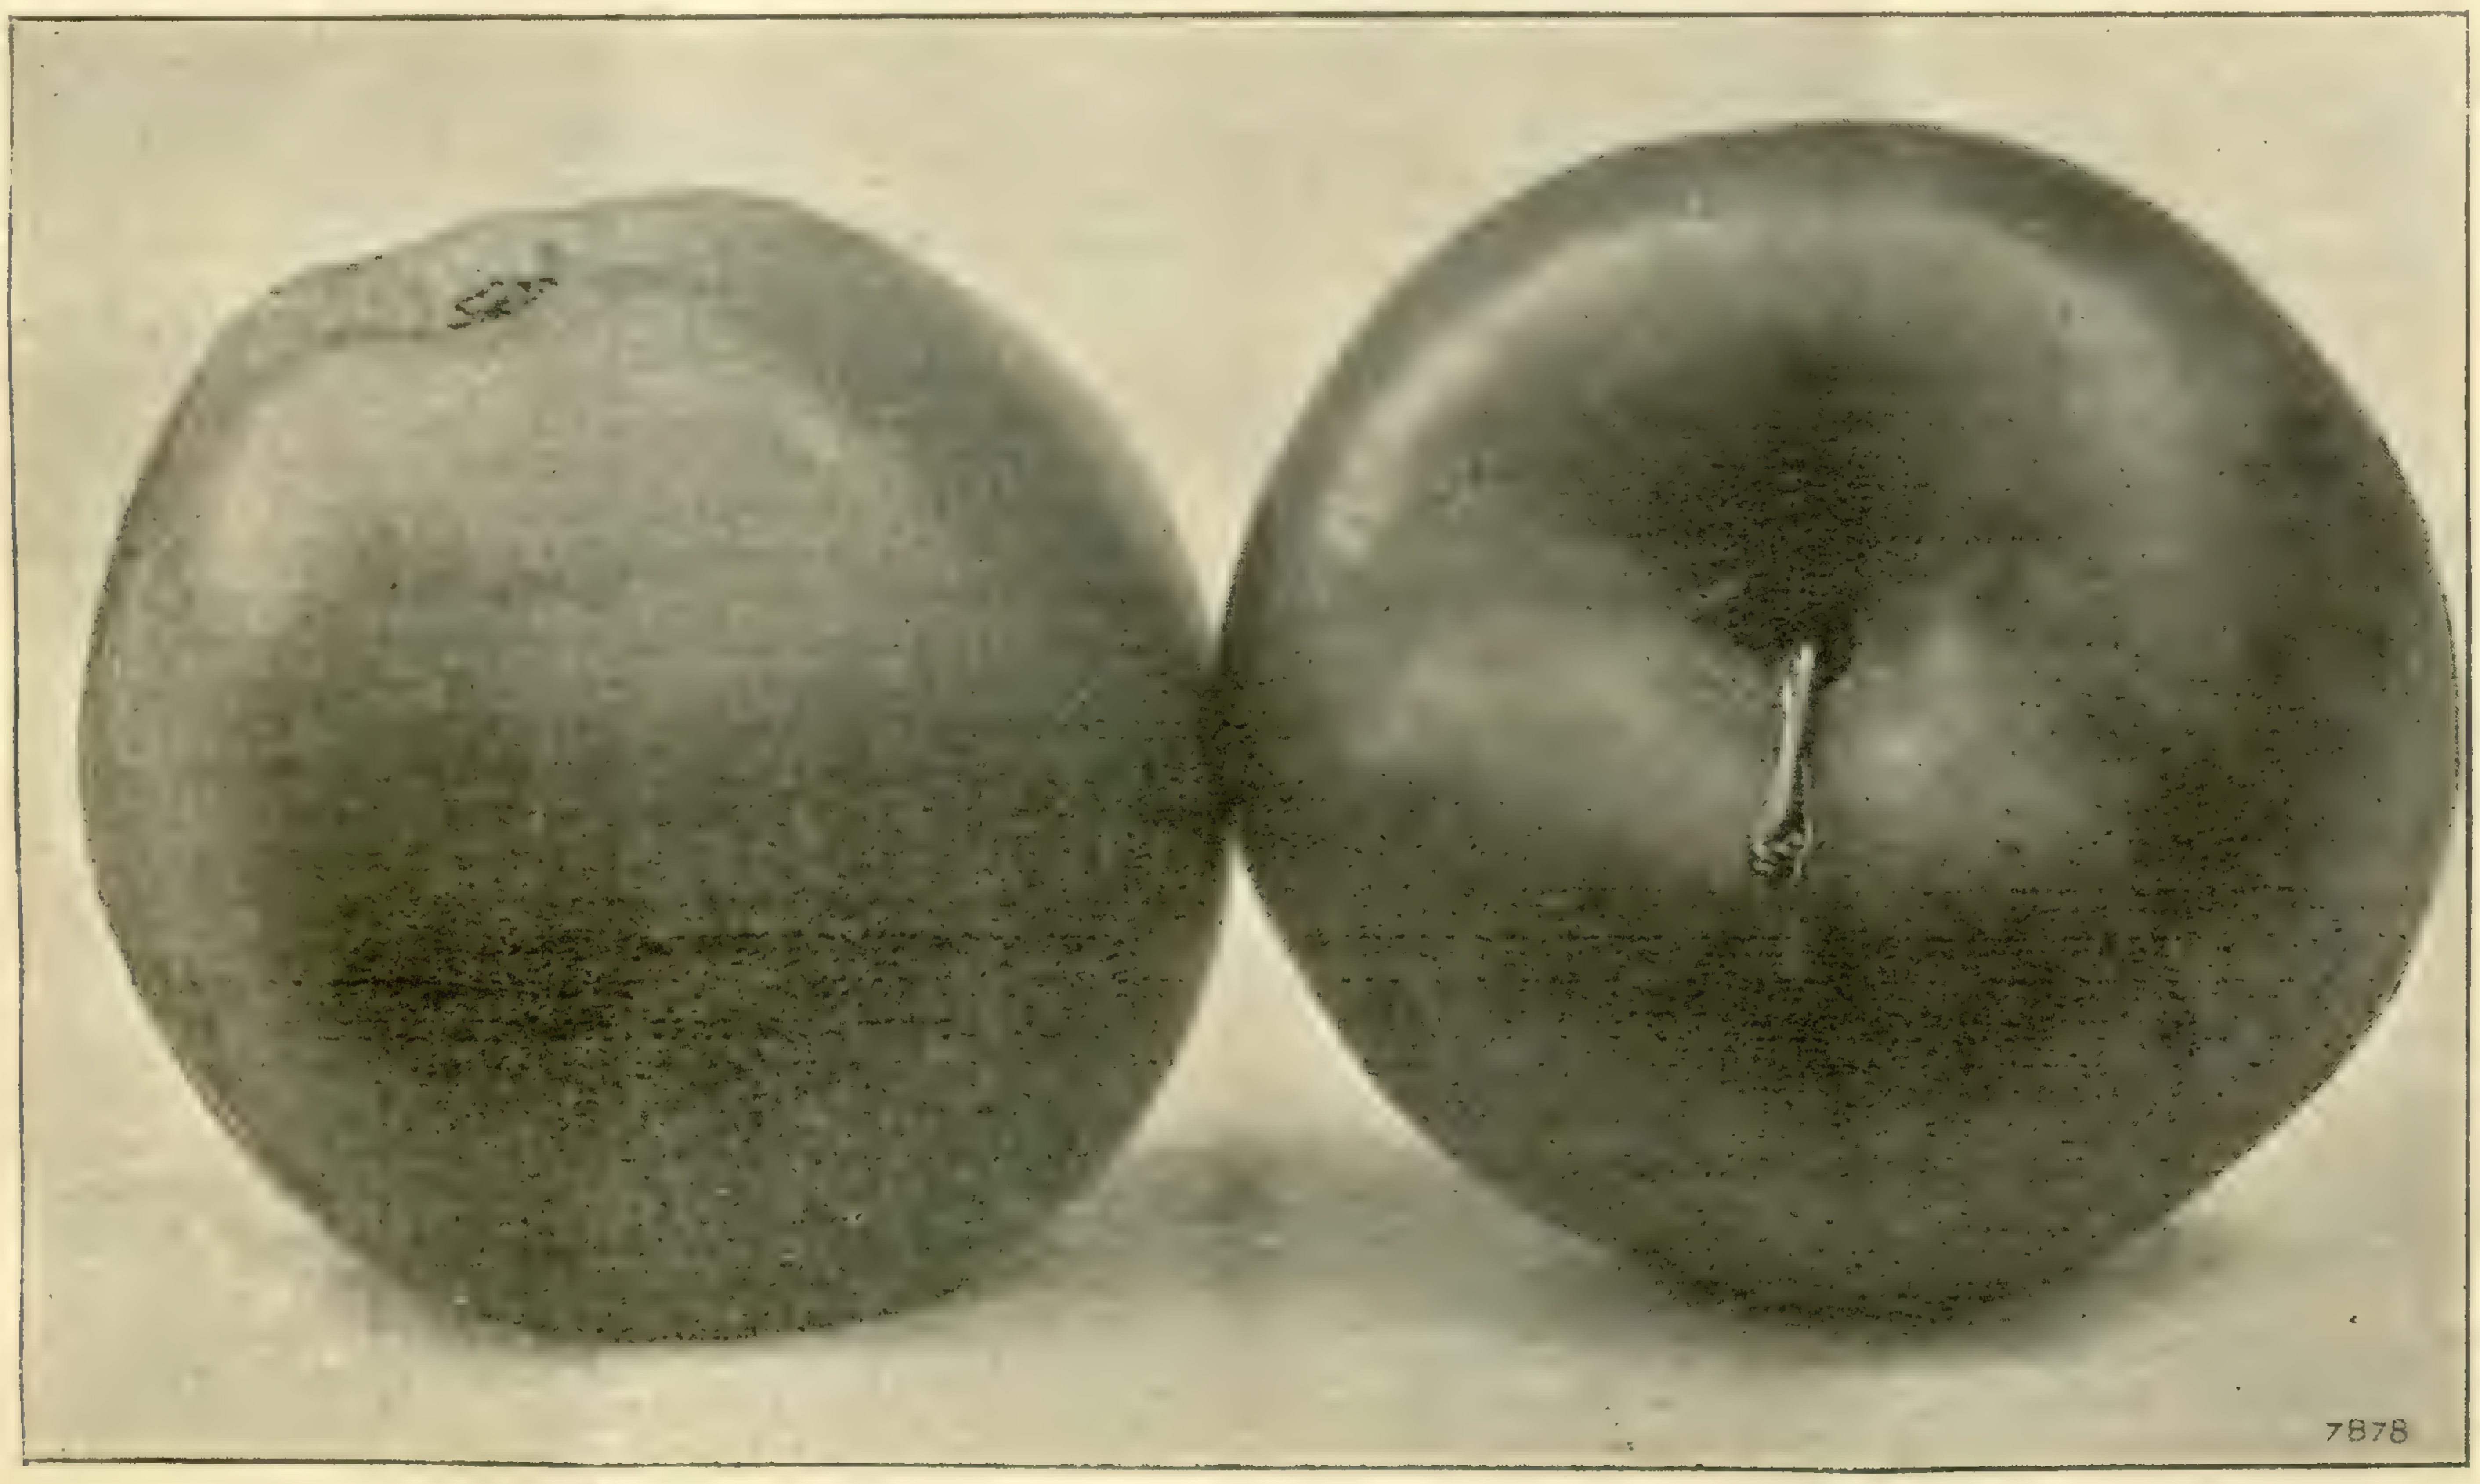
A very distinct species is N. Duffi, a native of Australia. In habit it is close and tufted, with thin rhizomes on which young plants are developed in quantity. The drooping character of the fronds, which are branched and slightly tasselled, giving it a peculiarity at once distinguishable. It grows about eighteen inches in height, and requires a stove treatment to succeed well. The fronds are said to never produce spores under cultivation, and must necessarily be propagated by divisions, and a somewhat lighter and more peaty compost is required for this species than the majority of this genus enjoy. Considering the usefulness and ease of culture of these plants, no collection of ferns can be complete without the more popular of their number; and for amateurs few can be more strongly recommended.

Edinburgh. R. L. HARROW.

The Ground Nut (*Apios tuberosa*) is a fairly common plant in this country, where its graceful twining growths bear numerous brownish purple and fragrant flowers during the summer. It is a leguminous plant, and requires support; it is perennial, and can be readily propagated by means of its pear-shaped tubers, which are numerous but not large. These are farinaceous and edible, but so far as we are aware they have not been used with any degree of success or popularity as a vegetable. A correspondent to *Garden and Forest* writes: "Having read of the edible character of the roots of Apios tuberosa I was curious to find out what they were like. This beautiful wild plant is familiar to all, but its curious tubers, strung along the underground shoots like beads on a string, are not so commonly known. I had used the plant to cover a bare wall near the house, and the other day I dug up a few of the tubers. They were about the size of small Seckel pears. I noticed that, even when slightly cut, or pricked, they exuded a gum-like juice, white and sweetish, something like India-rubber, in its elastic nature, and not easily dissolved in the mouth. Possibly this gum might prove to have some economic value. I baked the tubers in the oven for about fifteen minutes and found them delicious. When done they were mealy and creamy white in colour. Their flavour was strikingly delicate; something between that of a very fine potato and a sweet potato, with a suggestion of the chestnut, also. If farmers and market gardeners would take pains to cultivate Apios tuberosa they would undoubtedly make handsome profits, for the tubers would be in demand both as a novelty and as a welcome addition to our edible vegetables. It is not unlikely that, with cultivation, new varieties would be developed, perhaps approaching the sweet potato in size, and possibly even improving upon the present flavour."

DESSERT APPLE JAMES GRIEVE.

NOTWITHSTANDING the large number of dessert apples in cultivation, additions to the list that have the promise of usefulness invariably give rise to much interest, and when they prove, as in the case of the variety of which an illustration is given herewith, to be well adapted for general cultivation, they seldom fail to receive a warm welcome. We have a considerable degree of pleasure in directing the attention of our readers to this apple, for we have had it under observation, both in England and Scotland, for several years past, and as the result of our observations we have little doubt as to its proving of much value both for home use and market supplies, more especially in districts in which the famous Cox's Orange Pippin does not give complete satisfaction. James Grieve was raised in Messrs. Dickson and Co.'s Pilrig Nurseries, Edinburgh, and named after Mr. James Grieve, who was then manager of these nurseries, and is now engaged in business with his sons in the neighbourhood of the Scottish capital. It is described as having originated as a seedling from Cox's Orange Pippin, and both the growth and fruit partake of the character of that variety. The tree has a free branching habit, in the way of Cox's, but is decidedly more robust, and forms a vigorous and handsome natural pyramid. It is a heavy and sure cropper, trees on the paradise bearing freely when two years old, and in Messrs. G. Bunyard and Co.'s Nurseries, at Maidstone, the trees carried a fine crop in the summer of 1897, when the crop of the majority of the dessert apples was very light. The original tree in the last-named nurseries has not missed a crop during the five years that have elapsed since it was planted. The size and shape of the fruit is well shown in the accompanying illustration, which is a direct reproduction of a photograph that we had specially taken of two fruits, for which we have to thank Messrs. G. Bunyard and Co., who regard the variety with much favour. The skin is bright crimson on the side exposed to the sun, and rich yellow, marked with red, on the shaded side; the flesh is pale yellow, juicy, and although not quite so rich as that of Cox's, is very finely flavoured. The fruit commences to ripen in September, and the season extends to about the middle of November, the exact period during which the fruit may be had in perfection depending, as a matter of course, upon the locality in which it is produced. Messrs. Bunyard submitted the variety to the Fruit Committee of the Royal Horticultural Society on October 12, 1897, when an award of merit was made in its favour.



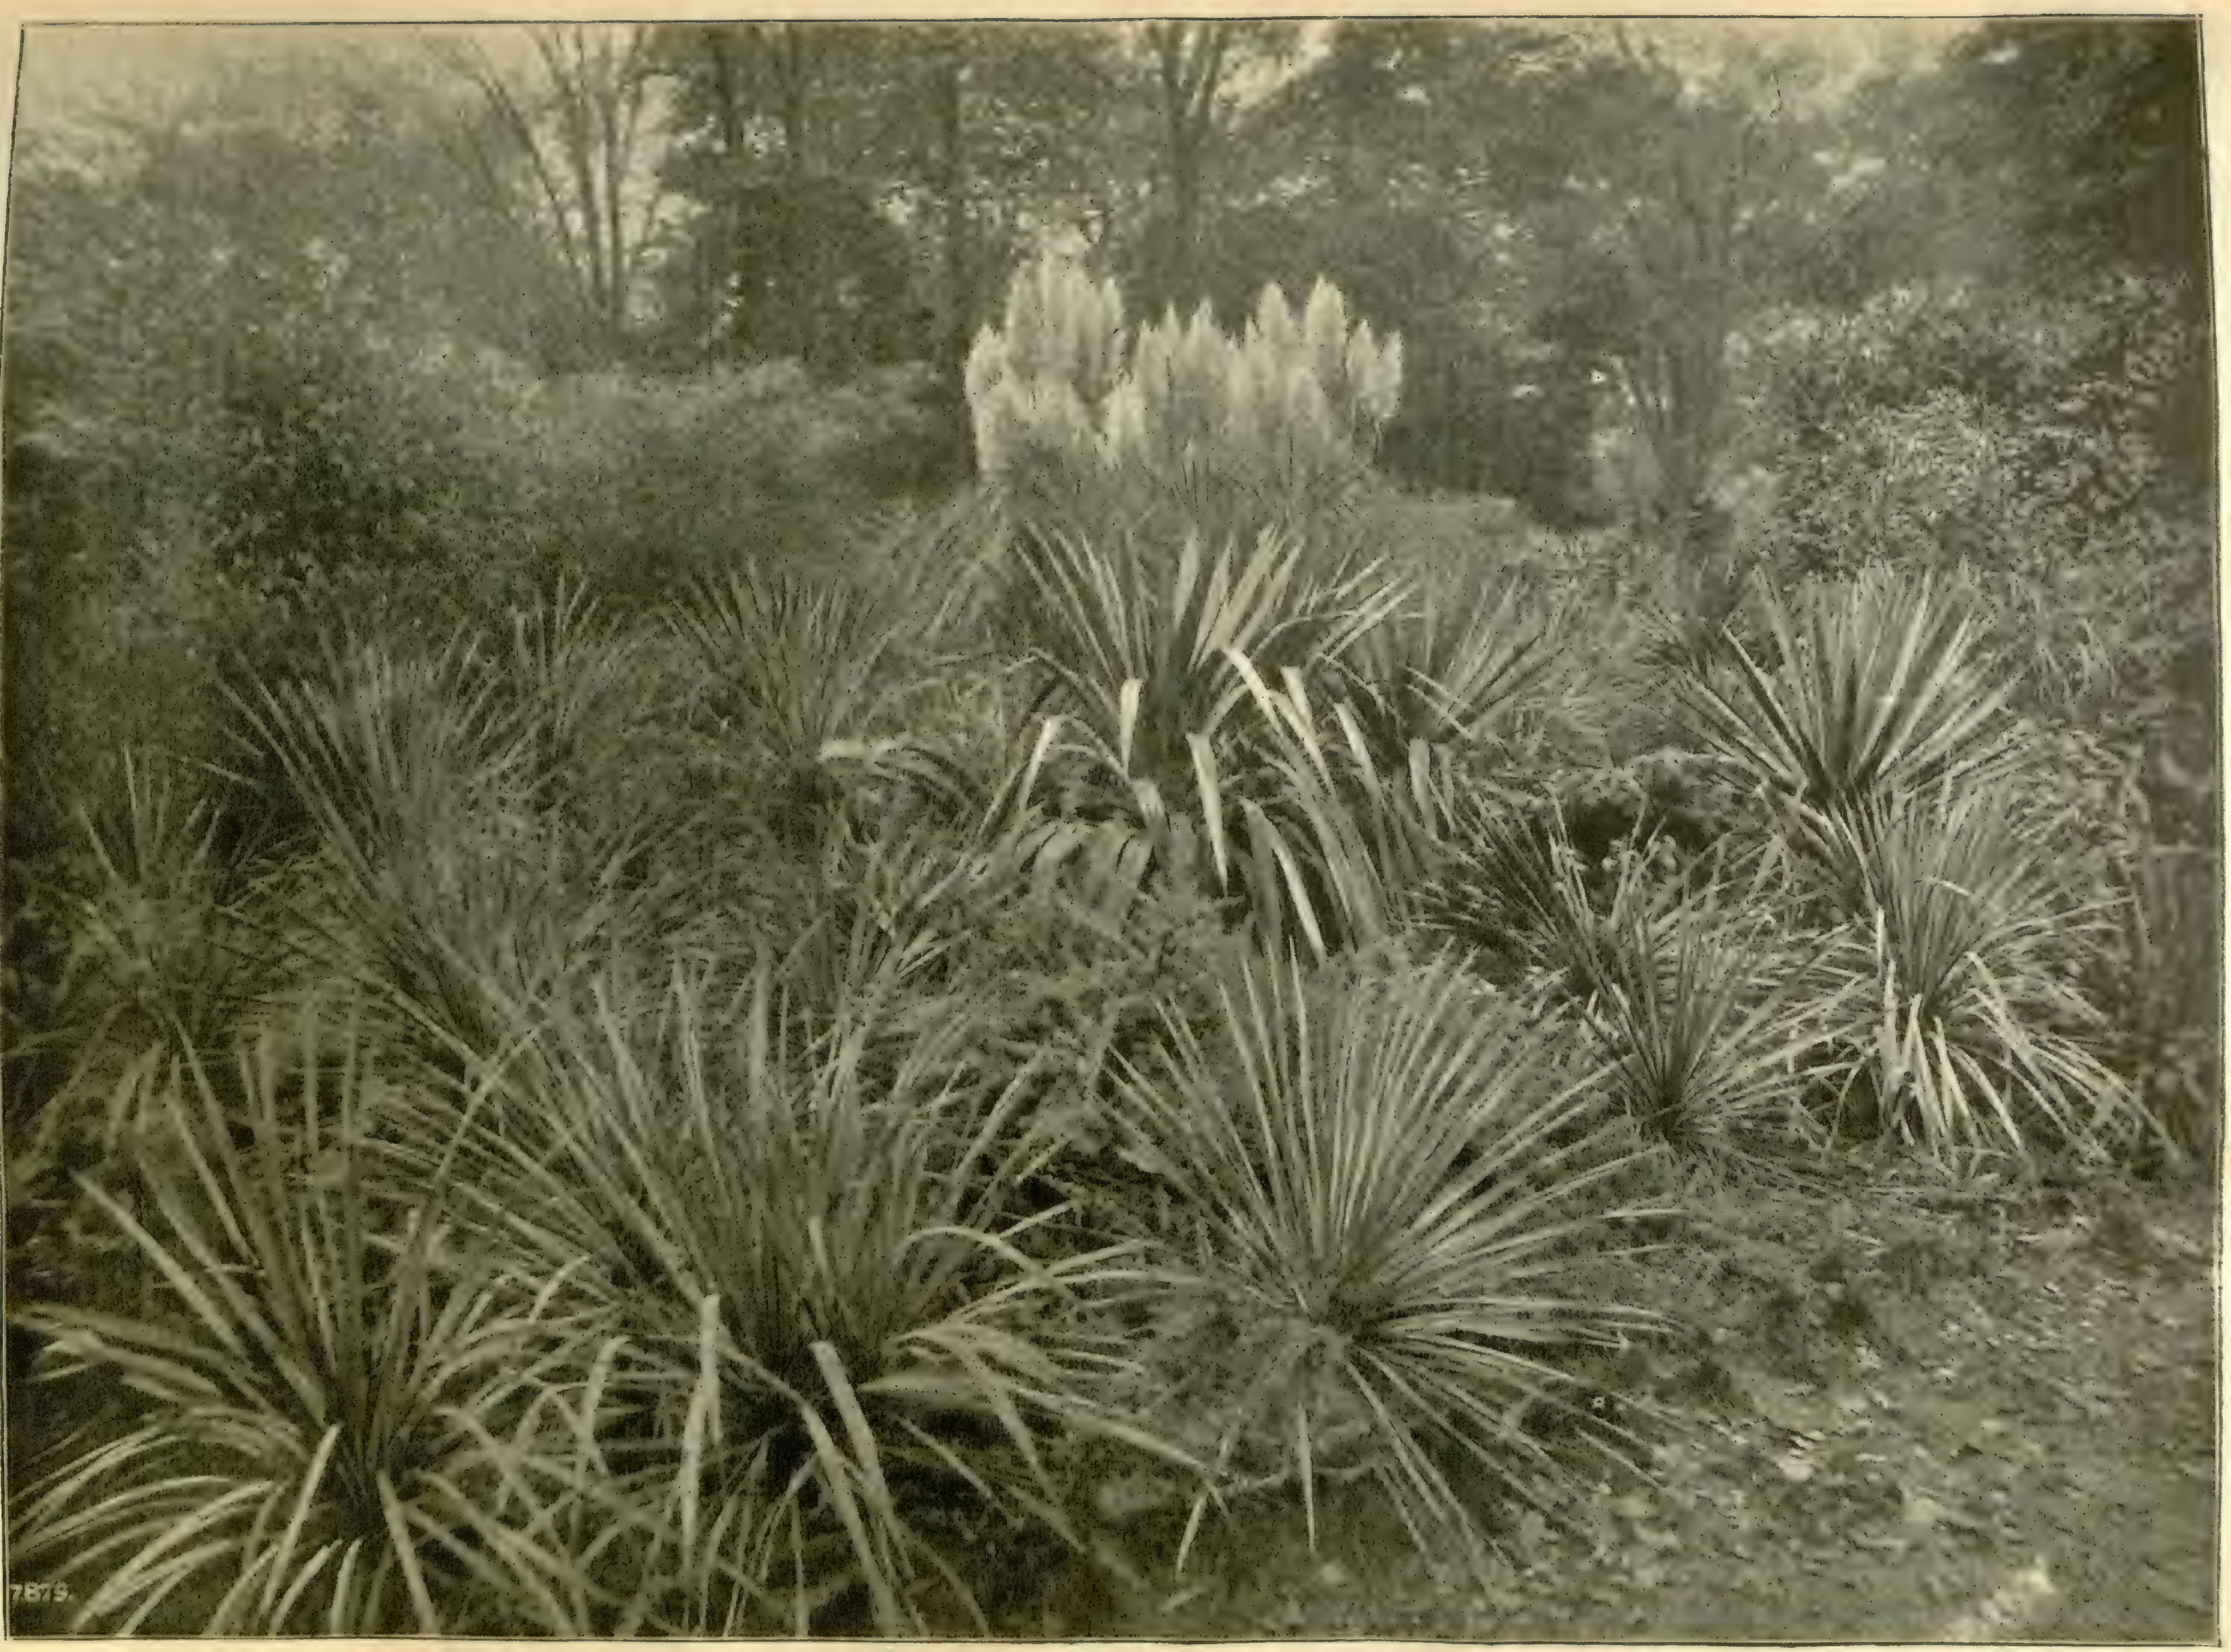
DESSERT APPLE JAMES GRIEVE.

Lady Gardeners.—At the annual council meeting of the women's branch of the Swanley College, held at Sir E. Sieveking's residence the other afternoon, Miss Goodrich Freer, the hon. secretary, presented a report of the work done during 1897. From this it appeared that forty-one women students had passed through the college during the year, and that no student had left the college properly certificated who had not been able at once to obtain remunerative employment. Four students have obtained places at Kew Gardens, three at the Royal Horticultural Gardens, Edinburgh, one is employed by Lady Henry Somerset at her home for inebriates at Duckshurst, and others are engaged by the Metropolitan Gardening Association and at convalescent homes and other public institutions. Sir Edward Sieveking heartily endorsed the medical opinion which he gave in the early days of the college six years ago that gardening was a most healthy and admirable employment for women. A conversation took place, and funds were asked for in order that a new road might be constructed close to the college, which, it was stated, would be an immense advantage to the students, and for the balance of the cost of a rose garden which is to be made under the direction of Dean Hole.

HARDY YUCCAS.

ALTHOUGH the species of yucca that possess a sufficiently robust constitution to admit of their being successfully cultivated without protection in the United Kingdom are comparatively few in number, they are all so distinct and handsome as to form a group of immense value for the embellishment of the flower garden. More especially are the hardy yuccas useful in enabling the planter to introduce widely divergent types of vegetation into garden scenery, and for giving a sub-tropical aspect to some part of the pleasure grounds. Their adaptability to positions of the most diverse character gives them still further claims for consideration, and with respect to this characteristic, it may be said that there is hardly a position in which a well-developed specimen would appear out of place. They are equally effective on the level, closely-shaven lawn and the irregularly arranged rockwork, and arranged in bold groups on sloping banks they present a highly attractive appearance, as so admirably portrayed in the accompanying illustration of a portion of one of the slopes surrounding the Bamboo Garden at Kew. The yuccas do not, it must be admitted, undergo the several changes which constitute so great a charm of deciduous trees and shrubs, and of the greater number of herbaceous plants; but they have attractions peculiar to themselves, and when grouped amid surroundings that bring their distinctive features into strong relief they seldom fail to attract attract attention or please the eye.

The most handsome and desirable of the hardy yuccas is unquestionably Yucca gloriosa, a species distinguished by a stately appearance both when in bloom and out of flower, and well deserving the high degree of popularity it enjoys, although it should not, as is so frequently the case, be grown to the exclusion of all the others. This yucca is too well known to require a detailed description, but it may be of interest to mention that it was the first species introduced to this country. The year of introduction is not known, but it was in cultivation in 1596, for Gerard includes it in the catalogue of plants grown in his garden which was issued in that year. In the first edition of his "Herball," published in 1597, he describes the species as "the root whereof the bread Casaua or Cazaua is made," and says with reference to it, "This plant groweth in all the tract of land from the Magellane Straights unto the Cape of Florida, and in most of the Ilands of the Canibals and others adjoining, from whence I had that plant brought mee that doth growe in my garden, by a servant of a learned and skilfull Apothacaire of Excester, Master Thomas Edwards." Johnson corrects Gerard in the amended edition of the "Herball," and says, "Our author . . . . committed these errours: First, in that hee saith it is the root whereof Cazaua bread was made when Lobel in his description said he thought it to be *Alia species a Yucca Indica ex qua pannis communis fit*. Secondly, in that he set downe the place out of the *Historia Lugd.* (who took it out of *Theuet*), endeavouring by that means to confound it with that there mentioned wheras he had his from Mr. Edwards his man. And thirdly (for which instead he was most blameworthy and wherein he most shewed his weaknesse) for that he doth confound it with the manihot or true yucca . . . within so few yeares after our author had set forth this worke it floured in his garden." Yucca gloriosa is a native of the eastern seaboard of the United States of America, and extends from Florida to North Carolina, growing freely in the drifting sands of the coast. Under cultivation in this country the plants attain to much larger dimensions than when growing in the native habitat of the species. After several years' growth plants occupying sunny positions usually bloom annually; sometimes, it must be confessed, too late in the autumn to admit of the perfect develop-



A BEAUTIFUL BANK OF HARDY YUCCAS IN THE ROYAL GARDENS, KEW.

ment of the flowers. When, however, they are produced, as is generally the case, early enough to escape the frosts and rains usually experienced during the latter part of the autumn well-developed specimens produce an exceedingly beautiful effect throughout the period they are in bloom. The branched panicles rise to a height ranging from three to five feet, bearing many hundreds of the large, goblet-shaped, creamy white flowers. Small groups, consisting of five or six plants of varying sizes are remarkably effective when arranged on knolls in prominent positions. The variety known as Y. gloriosa superba is dwarfer in growth than the type, flowers freely in a small state, and is so exceedingly beautiful as to merit attention. Yucca accuminata is similar in character to Y. gloriosa, and is decidedly handsome; the leaves range from eighteen inches to two feet in length, and are about two inches in breadth, and deep glaucous green. The flowers are greenish white, and produced in panicles rising to a height of four or five feet.

Hardly less valuable than the preceding species is Yucca recurvifolia, an elegant form known also in gardens as Y. japonica, Y. pendula, Y. recurva, and Y. reflexa. This desirable species has a rather short stem and leaves ranging from two to three feet long, deep green, glaucous green when young, less stout in texture than are those of Y. gloriosa, and elegantly recurving. This peculiarity renders the species highly attractive when grown as a single specimen upon the lawn, or in suitable positions in geometric flower gardens; and of special value for rustic and other vases. It is free in blooming, producing large, handsome panicles of flowers and is perfectly hardy. Y. recurvifolia has been in cultivation rather more than one hundred years, having been introduced to this country in 1794 from the coast of Georgia. Yucca glauca is a North American species, with leaves ranging from fifteen to eighteen inches long and one and a-half inches broad, and producing much-branched panicles of whitish flowers. It is not, perhaps, so hardy as the foregoing species, but it will thrive out of doors in the southern and western counties in well-drained soil.

Especially desirable also, in the smallest collection is the Silk Grass (*Yucca filamentosa*), which has long been in cultivation, having been introduced from North America in 1675. This species is almost stemless, and produces dense rosettes, consisting of from forty to fifty leaves, which have an average length of twenty inches and breadth of one and three-quarter inches, and are bright green, with thread-like filaments along the margins. The flowers are white, suffused with green on the outside, and borne in an elegant panicle on a slender stem rising to a height of five or six feet. There are several handsome varieties of this distinct species; the form variously known as grandiflora, major and maxima being remarkable for the large size of the flowers; and aureo-variegata is one of the most beautiful of hardy plants with variegated foliage, the leaves being marked with longitudinal bands of rich golden yellow. Although usually described in the books as a greenhouse plant, and frequently so grown, the last-named is quite hardy and may be successfully cultivated out of doors in well-drained soil. Y. filamentosa is quite hardy, but it is less able to resist the injurious effects of an excess of moisture about it than the other species mentioned, and it is therefore important to plant it and the several varieties in well-drained soil. Planted on mounds and the lower ledges of the rockery, it will grow freely and present a highly attractive appearance at all stages of growth.

The cultivation of the hardy yuccas is of the simplest, and can be described in very few words. They can all be multiplied by means of suckers, side growths, and root cuttings, and they all thrive in a deep sandy loam. The two essential points in their cultivation are to provide a liberal quantity of soil for the roots, whether on the level on mounds or on rockeries, and thoroughly efficient drainage. On naturally cold and wet soils they should be planted on beds raised well above the surface and when the soil is very light they should receive during the season of growth, two or three liberal supplies of water. G.

COX'S ORANGE PIPPIN APPLE.

THIS is one of the best, if not actually the best, dessert apple in cultivation. It is indispensable to a select collection of dessert varieties, and it does well and bears freely on young bush trees on the English paradise stock. During the summer of 1897, when apples were unusually scarce, good crops of Cox's Orange Pippin could be met with in some of the southern districts of England.

This is a much older apple in point of time than is generally supposed, for it was in 1830 the late Mr. Cox, of Colnbrook Lawn, Bucks, raised it from a pip of the Ribston Pippin, and from a pip of several which were sown at the time Cox's Pomona was obtained; and thus two standard apples of very opposite character resulted from the sowing of nine seeds. This was in remarkable contrast to the experience of Mr. T. A. Knight some years before, who planted thousands of seedlings, out of which the Downton Pippin was the only variety worthy of note.

Cox's Orange Pippin was first propagated by Mr. Small, when proprietor of the Colnbrook Nursery, but was not disseminated further than the locality where it was raised. It was not until something like twenty-four years after it had been raised that it attracted the attention of the late Mr. Charles Turner, Royal Nursery, Slough, by whom it was largely distributed. So high an opinion had Mr. Turner of the apple, that he grew it much for his own eating, and seemed to be never without some in his pocket while the supply lasted.

The fruit may be briefly described as very handsome in appearance, with a firm yellow flesh, very tender, juicy and saccharine, with a rich aromatic flavour, more so than the Ribston Pippin possesses, and the flesh is rarely so hard and tough as is sometimes the case with the latter. Its season for use is from October till January, but it will often keep in good condition until a later period. It is generally thought to be a small-sized fruit, but quite large ones have been met with. I remember some many years ago which averaged eleven inches in circumference.

R. DEAN.

LIME AND LIMING.

ACCORDING to early Roman writers, lime and gypsum were employed for agricultural purposes more than two thousand years ago. In England liming has long been resorted to with great profit upon certain soils. It is stated that the soils of more than one-fifth of the entire area of France are derived from granite, and when the phosphoric acid and lime, which they lack, are applied, a complete transformation results, the character of the vegetation being so changed, that good crops are obtainable where only meagre ones were grown before.

In the course of a series of experiments, more than one hundred varieties of plants have been tested to find out what effect lime has upon their growth, and while a few were injured by it, particularly if they are grown the same season that the lime is applied, most of the plants were either uninjured by liming, or else benefited in a greater or less degree.

The experiments showed that lime, to be of the greatest possible use, must be applied to the land in the form of air or water slaked lime, or of carbonate of lime (chalk).

Lime unites with acid substances in the soil, by which the soil is sweetened, or its natural sourness overcome or reduced.

In case certain injurious iron compounds are present in the soil, these are so transformed by lime as to be rendered harmless. It also acts upon potash compounds in the soil in such a way that the lime takes the place of the potash, setting the latter free for the use of plants.

If lime is present in a soil to which ordinary commercial fertilisers, such as superphosphates have been added, it is probable that some of the soluble phosphoric acid will further combine with lime, in which condition it would be expected to be more readily available to plants than would have been the case had lime been absent, and a more favourable opportunity been given for all of the phosphoric acid not quickly utilised by the plants, to combine with the other minerals present in the soil.

The presence of lime in soils further favours the decomposition of the organic matter which they contain, and in this process carbonic acid is produced, which in turn acts upon the ingredients of the soils in such a way as to render the natural plant food much more readily assimilable. It plays, likewise, an important part in facilitating the changes of ammonia into nitric acid, or, in other words, in placing at the disposal of plants the stored-up nitrogen of the soil, as well as that applied to or left in it, in the form of animal or vegetable refuse.

It should be stated as a caution, that it is probable excessive amounts of caustic lime might prove injurious to certain plants which are ordinarily helped by it, particularly if the soil were but slightly or not at all acid. It has been found that even moderate dressings of lime favour the growth of the potato scab fungus, a minute organism which, by its development upon the surface of potato tubers, causes them to become scabbed or covered with rough and more or less deep excrescences. On this account, liming in a garden rotation which includes potatos, should be indulged in but moderately, and the application should follow the potato crop immediately, and never applied direct for the potato crop.

Lime applied to stiff clays causes them to become more friable, more permeable to the air, easier of working, and better capable of supplying water to plants as needed. Sandy soils, on the other hand, are rendered by it more compact and more retentive of water and manurial substances. On very dry, sandy soils, smaller applications of lime must be made than upon moist soils, and the use of large quantities of lime upon such soils in single applications is not advisable.

If the lime is thoroughly worked into the soil it may be applied in the spring, for certain plants, with little or no risk, and usually with great advantage. This seems to hold true of beets and turnips of all kinds, lettuce, spinach, cauliflower, cabbage, onions, and many other plants. If the soil is very sour, as in some very old kitchen gardens, then the use of lime immediately before the crops are sown in spring, may prove of great service, for the reason that the lime facilitates the transformation of the nitrogen into a form immediately assimilable by the plant.

Harpenden. J. J. WILLIS.

Sugars in Beetroot.—Herr F. Strohmer gives some interesting particulars relating to the production of sugars in his recent paper on the subject. He observes: The views to which expression was given thirty years ago by H. Schacht, that the quality of beetroots depends on the number of developed leaves and the length of life of the plant, are now found to be free from objections. Sugar is produced in the leaves, either directly as reducing sugar, or from starch or other carbohydrate, and migrates through the leaf stems to the root. The production of sugar depends on the amount of light, and the form and position of the leaves are of importance. When the sunlight passed through white or yellow glass, leaf production was vigorous, but with blue or red glass feeble; and the weight of roots under the influence of yellow light was nearly twice as great as when blue and red light were employed. The percentage of sugar under the different conditions was 7·4—8·1 with yellow, 6·4—7·4 with red, and 8·0—8·4 with blue light. For producing total organic substance in beetroot, rays of medium wave-length are the most favourable, but for converting the products of assimilation into sugar, the so-called chemical rays seem to have a prominent rôle. The results of field experiments showed that sugar production begins at an early stage in the leaves, but is greatest from the beginning of August to the middle of September. Under favourable conditions, there may be a not inconsiderable accumulation of sugar even later. From the beginning of July, the sum of the percentages of water and sugar in the roots is constant. This, and the fact that the percentage of sugar in the roots increases until the leaves die, indicates that the sugar, once stored in the roots, remains there. It is only when the roots are taken out of the soil and the leaves cut off that the sugar begins to be used up in maintaining the life of the plant and in preparation for following year's growth.

Lily of the Valley Forcing.

The following is the text of the paper read by Mr. T. Jannock, of Dersingham, at a meeting of R.H.S., as given in the society's journal :—

Of the thousand and one plants which submit to be forced into flower out of their season it may be doubted if there is one of anything like the universal popularity which the lily of the valley enjoys. Its history as a "forcer" goes back to half a century ago, when clumps of lilies were grown in Berlin and Hamburg in a small way to get a few blooms for Christmas and New Year. By 1856 between twenty and thirty nurserymen in and around Berlin had taken up the cultivation, but in all cases only on a small scale. In 1859-60 the largest quantity of flowering crowns that any one nurseryman produced annually was sixty thousand ; but this gradually increased until in 1870 seventy-two acres were under cultivation in lilies outside the city of Berlin. At the present moment there are on the Continent and in England many thousands of acres devoted solely to the production of lily of the valley crowns.

In order to be successful in forcing lilies of the valley the culture of the crowns demands the first consideration. I have seen lilies grow in almost every kind of soil and situation, doing better in some than in others ; but experience has taught me that the best soil for growing crowns for forcing purposes is a light sandy loam, with a damp subsoil ; and the best situation is an open one to the south and west, sheltered, if possible, from the east and north. In cold and heavy clay land they will not do well ; they will grow, and sometimes produce very strong crowns, with but few fibrous roots ; but such crowns are not fit for early forcing, as, owing to the nature of the soil, they are kept growing too long, and do not ripen off early enough.

The ground must be deeply dug and well broken at the same time, working in plenty of old hotbed manure, linings, rotten leaves, &c., all well decomposed and crumbled to pieces. This work should be done in the autumn in dry weather, in order to be ready for planting as soon as crowns can be obtained. I greatly prefer autumn planting, considering that the sooner the crowns are in the ground the better. Nothing is more injurious to the roots of lilies than exposure to sun and wind. I have been compelled sometimes to plant in March in drying east winds with bright sunshine, when it has been impossible to get the roots covered quickly enough to prevent their getting dry, and the consequences have been disastrous.

The ground having been prepared, the best and quickest method of planting is in rows seven or eight inches apart, the plants being about one inch apart in the rows ; paths of fifteen to eighteen inches wide may be left between every eight rows for the convenience of weeding. In planting, which is done by throwing out trenches about five inches deep, take care that the crowns are not set too deep ; they should be only just deep enough for the tips of the crowns to be level with the surface of the ground. A good mulching of cow manure. or, if this cannot be had, well-rotted stable manure, completes the work, and nothing further is required but keeping the beds free from weeds and giving them plenty of water in dry weather during the summer.

If one-year-old crowns have been selected for the start, they will require three seasons of growth before being fit to be lifted for forcing. It must not be supposed that so-called one-year-old crowns are actually twelve months old ; they really represent only four to five months' growth, the rhizomes beginning to grow in June or July, forming the crown under ground during the summer. Thus when they are fit to lift as flowering crowns their actual age is three and a half years. It is true that by good cultivation many of these crowns will bloom in two years from the time of planting, and many growers have been tempted to lift them at that age ; but experience has taught me that the percentage of flowering crowns is smaller and the increase of planting crowns less than when they are left a year longer undisturbed. It is generally understood that lilies of the valley must be three years old before they flower, and that they will then flower every alternate year. This is the rule, but there are exceptions. By good cultivation—*i.e.* high feeding at the proper time with liquid manure—and if special care is taken to remove the flower as soon as ever it is open, by pulling its stalk right out of the crown, such crowns will bloom several years in succession ; and hence it is obvious that lily crowns can be made to bloom twice within twelve months, viz., once at their natural time in May, and again taken up in the following autumn and forced into bloom before January.

To force lilies of the valley successfully it is of the utmost importance to have well-ripened and well-matured crowns that have fully completed their growth and are perfectly at rest. Before they have undergone a period of rest, be it ever so short, you cannot force them, no matter what amount of heat you may give them. Much also depends on where and how the crowns have been grown. The best are undoubtedly those that have been grown in light sandy soil, heavily manured and well exposed to the sun, as they will complete their growth and go sooner to rest than those grown in heavy soil and shady places.

Forcing operations may commence about the end of October or beginning of November ; the methods adopted are various, but for early flowers, in November and December, a close propagating or forcing pit is absolutely necessary, in order to maintain a moist and even temperature. If pots are used plant about twelve crowns in a five-inch pot in the following manner : Place four crowns in the palm of your left hand, then a layer of soil on the roots, again four crowns and more soil, and then the remaining four crowns, keeping the crowns all level ; close your hand and drop the whole into a five-inch pot, working the soil well in between each crown, so as to have them equally divided and all crowns standing level just above the brim of the pot. Give them a good watering, and plunge the pots in a bed of either moss or cocoanut fibre ; cover lightly with two or three inches of clean moss, and close the bed with boards, to keep it perfectly dark. Bring the bottom heat up to 80 degrees Fahrenheit at once, and gradually increase to 95 degrees within a fortnight, maintaining a regular and even temperature the while. Never allow the thermometer to rise above 100 degrees or to fall below 80 degrees, or harm will be done. Examine the pots daily ; keep a moist atmosphere ; and water (when necessary) with water of exactly the same temperature as the bottom heat in which they are plunged. When the crowns start into growth, and are about two inches high, remove the top covering of moss and gradually inure them to the light, still, of course, maintaining a high temperature. As soon as the bottom bells begin to open remove to a cooler temperature, and discontinue syringing overhead, as moisture hanging on the blooms is apt to spot the bells.

Another method, more usually adopted, and which saves much labour and room, is by planting the crowns an inch apart in boxes of a convenient size and treating as above.

Still another plan, but one which is not often practised now, is to plant the crowns in forcing beds thickly together, and when they have grown two or three inches to transplant them into pots.

It may be here mentioned that actual flowering can be retarded, when so desired, by the boxes in which the crowns are forced being removed from the forcing-house into a cooler one of genial temperature. The heat, however, must be always even and not too low, or else the damp will speedily ruin the flowers.

The foregoing methods refer principally to the early period, before Christmas ; later in the season, and as the spring advances, forcing is an easier matter. The temperature need not be kept so regular, and all that is required is warmth and moisture, which will soon start the crowns into growth. More attention should at this later time be paid to the hardening off, shading from bright sunshine, and never allowing them to get dry at the roots ; they should also have more room by planting the crowns wider apart, as more leaves will now appear than before Christmas.

Finally, it should be pointed out that if temporary frames are placed over the beds of flowering crowns out of doors in March their blooming will be hastened by two or three weeks. For this purpose keeping them close and watering as required are the only necessary directions.

It is quite immaterial in what soil the crowns are planted for forcing, as absolutely no new roots are formed during this period ; anything, in fact, which retains moisture will do. You cannot improve the blooms by planting the crowns in the very best of soil, or by giving them manure water. All the nutriment required for the development of the flowers is gathered during the previous growing season, and is stored up in the roots.

It is not generally known that forced lilies will bear almost any rough treatment. They can be pulled out of their boxes or pots when in full bloom for making up into fancy stands, ornamental pots, and nicknacks of any description without flagging or spoiling. They can be sent by post or rail hundreds of miles, packed in a little damp moss, when they may be again planted, and will look as fresh as if they had never been disturbed. I once sent a quantity in an hermetically-sealed box to Pietermaritzburg, where they arrived after their long ocean and land journey as fresh as if they had only travelled a few miles.

As regards the varieties or "strains" best adapted for forcing, that known as the Berlin is unquestionably the best for early work. The Dutch and Hamburg ones are good for late forcing, but my experience is that they do not approach the Berlin strain for forcing before Christmas. These three varieties are said to be seedlings, or possibly "sports," from the common or wild lily of the valley, on which they are immense improvements. No amount of cultivation would ever transform the wild plant into a rival of either the Hamburg, the Berlin, or the Dutch forms. The Dutch variety is of more spindly growth than the Berlin, and has, moreover, a weak and drawn appearance.

In conclusion let me say one word on the subject of retarding. Dr Lardner once pooh-poohed the idea of a steamship ever crossing the Atlantic, and the idea of retarding lily of the valley crowns may appear just as absurd to the casual observer. That it is now done, however, both extensively and successfully, is too well known for me to emphasise.

The Weather Plant.

Abrus precatorius. (L.)

To judge by a recent notice in no less a journal than the *Times* this must be a very marvellous plant, since, according to the discoverer of its wonderful powers it is able by its movements to indicate the weather of the locality not only forty-eight hours in advance, but also the hourly variation during that period. Not content with this, to judge by the notice in question, and the circular issued by Mr. Nowack, it predicts, or rather enables him to predict, cyclones in America three days beforehand, actually naming the cities they will visit ; earthquakes in Japan, and volcanic eruptions in Sicily are also foretold several months in advance, and warnings of colliery explosions are given long before they occurred, with precise indication of the county which was to be the sufferer. In confirmation of these marvels we have a large number of names cited, whose owners in most cases appear to be extremely careful not to commit themselves ; and a variety of press cuttings, most of which are of that delightfully vague and unscientific character which results from a paragraph going the round of the press and being paraphrased by the various writers according to their fancy, in the absence of any actual personal knowledge of the matter in hand.

Abrus precatorius (L.), or the wild liquorice, derives its generic name from the softness and delicacy of its foliage (*abros*), and its specific name (*precatorius*) from the fact that its seeds are used for rosaries. Its illustrious sponsor, Linnæus, was, therefore obviously unaware of its astounding sagacity as a weather and earthquake prophet, or its implied sympathy with the sun in its spotted condition, and it is only in its affinity with the sensitive plant as one of the mimosæ that we get any suggestion of its extraordinary powers. Unfortunately for the curious in such matters, neither the *Times* notice nor Mr. Nowack's circular affords the least information as to "how it is done ;" and although the modest sum of £10,000 is called for to build an observatory for the proper exploitation of these wonders for the benefit of mankind, no idea is given why so much is required for so apparently simple an object as watching the gifted plant and interpreting its signals according to the code which, presumably, the discoverer has managed to decipher. Most epoch-making discoveries are in the air as it were some time before they are crystallised into utilisable facts ; scientists have been on the borderland long before, numerous papers very near the mark have been written, read, and published, and the world is therefore more or less prepared to accept them when eventually defined and clearly established. Here, however, although the said discoveries and experiments extend over a decade, not a quotation appears from a single truly scientific journal, and a certificate of accuracy to the extent of 96 per cent. of the predictions which was promised by the committee of the (Vienna) Jubilee Exhibition in 1888 does not appear to have been given, or presumably it would have been reproduced.

Mr. Nowack, who is an Austrian, and does not apparently claim connection with any scientific society, is now in London with a view to establishing the weather-plant observatory in question ; but we certainly think he will have to adopt some far more scientific and convincing fashion of bringing his discoveries forward before he will obtain any adequate support for the exploitation of his plant. C. T. D.

VARIETAL DEVELOPMENT IN BRITISH FERNS.

DR. F. W. STANSFIELD, President of the British Pteridological Society, devoted his presidential address at the annual meeting of the society to the development of varietal forms. He said: The history of British fern varieties is almost wholly comprised within the last fifty years. Before 1850 only some half dozen to half a score of varieties seem to have been recognised. Polypodium vulgare cambricum, described as a species by Linnæus, was first recognised as a variety by Willdenow. It is first referred to in print in the "British Herbal," published in 1743. P. v. semilacerum and Asplenium trichomanes incisum are about equally ancient. Lastrea paleacea cristata, Polystichum angulare proliferum (now acutilobum proliferum, Choule) were known at Kew in 1850, and probably Scolopendrium vulgare marginatum, though I have not been able to find any reference to this last. L. paleacea Pinderi, according to "Ferns of the Lake District," was found in 1841, but possibly this is a misprint. A crested form of Lady Fern is said to have been growing on Winchester Cathedral from time immemorial. The earliest variety of whose origin there is explicit record is Polypodium vulgare omnilacerum, found by a Mr. Bennett in 1848. When seen in its best character this is still one of the grandest of polypodies, but unfortunately it has a bad habit of subsiding from its handsome deeply lacerate character into a poor serrate form; it is consequently but seldom seen in collections, and still more rarely in its best form.

In 1850 my late friend, Mr. Edwin Fox, found a reflexed athyrium in S. Devon. This may now seem a very small achievement to us who have probably all found reflex forms of the Lady Fern, but it is important as indicating the beginning of systematic fern hunting. In 1851 appeared the still well-known favourite Scolopendrium vulgare laceratum, found by a Mr. Young in Somerset. Also Mr. Wollaston appeared on the warpath, and found his first Blechnum spicant trinervium. In 1852 the same hunter found his grand acutilobe angulare, which was first known as Polystichum angulare proliferum Wollastoni. This was memorable, not only as a good thing in itself, but still more as being the forerunner of the bewildering multitude of lovely forms of angulare with divided lobes, since classified into acutilobes, multilobes, divisilobes, &c., but for long lumped together as "proliferums." In the same year was found a crispy and sometimes multifid form of Bristle Fern by Colonel Lowe. In 1853 Mr. Wollaston found his first Blechnum spicant cristatum. In 1854 appeared quite a number of new and good varieties, of which, perhaps, the most noticeable was Polystichum angulare brachiato-cristatum, Grey—still, when true, the finest of its race, but unfortunately a little inconstant in its character. Probably at least a dozen other finds of brachiato-cristatum have since been made, many of them irregular and unworthy of cultivation, but in almost all there is the same association of characters, viz., the brachiate and crested and with them a peculiar toothing or cutting and shortening of the pinnules different from that of any other group of varieties. This is a singular and unexplained association, but the varieties are far too numerous for it to be considered mere coincidence. In the same year, 1854, Elworthy found his truncate cruciate angulare. Also two fine polypodies were discovered, viz., the old cristatum and the miffy little plant named multifido-cristatum by Moore but more correctly afterwards grandiceps Parker, by Wollaston. Every fern grower is familiar with the former, but the latter is still rare, and, indeed, has always been rare.

In 1855 was found Lastrea paleacea Scholfieldi, a dwarf ramose variety, from which ten years afterwards sported the beautiful little ramulosissima. In the same year, as recorded by Mr. Lowe, Asplenium lanceolatum microdon was first found by Miss Wilkinson. Several other plants of this curious form were afterwards found by C. Jackson and others, as also of the corresponding form of A. adiantum-nigrum. These forms are regarded by Mr. Wollaston and Mr. Lowe as "undoubted hybrids with A. marinum," though it is by no means clear upon what grounds this confident opinion is based. It is true that they are both apparently barren, but barrenness is by no means exclusively confined to hybrids, and even if it were, it is still possible that these forms may eventually turn out, like many other varieties once thought to be sterile, to be not barren after all. This is a problem which those of us (alas! too few) who have leisure and room to spare should try to settle—on the one hand by trying to raise hybrids between, say, lanceolatum and marinum, and on the other hand by endeavouring to raise offspring from spores or by apospory from microdon. I do not say the hybrid theory is wrong, but it is a case of "not proven."

In 1856 Elworty found his Polystichum angulare plumosum. According to Colonel Jones, C. Jackson was the first discoverer of a plumose angulare. Mr. Wollaston also found one, which is the best known and most widely diffused on account of its fertility. The next year, 1857, produced Lastrea filix-mas Bollandiæ, still, so far as I know, the only truly and purely plumose form of the species. Also the very distinct Athyrium filix-fœmina Frisellîæ, and the marvellous Scolopendrium vulgare Claphami, the earliest type of the fimbriate crispum. This was found not by Mr. Clapham but by that gentleman's coachman, Thomas Smith. This year, 1857, also saw the accidental discovery of a good standard fern, Osmunda regalis cristata. It was rooted up by a fern-collector named John Lloyd, and sold among others in a wholesale lot to Messrs. Osborn, of Fulham, both vendor and purchasers being at the time equally unconscious of the prize with which they were dealing.

The year 1858 produced Polystichum aculeatam acrocladon and Scolopendrium vulgare limbospermo-cristatum of Elworthy, the last a form which is now rarely seen and of which much is not generally thought, but which when seen at its best, as I remember to have seen it, is a lovely thing, with long narrow fronds and complex lace-like crests. In 1859 the famous Scolopendrium vulgare Stansfieldi appeared, a crispum-fimbriatum, which was inquired for in vain many years after it had ceased to exist as a distinct variety. In this year also Mr. Clapham found his Asplenium trichomanes incisum, a beautiful and distinct form afterwards known as incisum Claphami, and which so far as I remember resembled very closely my grandfather's incisum triangulare found nine years later.

The year 1860 was a veritable *annus mirabilis* in the fern world, being memorable for the discovery of Horsfall's plumose Lady fern as well as the Axminster plumosum; Monkman's Athyrium filix-fœmina acrocladon; A. f.-f. Fieldiæ (the first truly cruciate Athyrium); Polystichum angulare cristatum, Mrs. Thompson (better known as Thompsoniæ); Elworthy's P. a. rotundatum; Grey's brachiatum (not brachiato-cristatum); P. a. Wakeleyanum (cruciato-cristatum); Scolopendrium vulgare ramo-marginatum of Clapham; S. v. digitatum J. Crossfield, and Blechnum sp. cristatum of Huddert. The three Lady ferns first mentioned are still in the front rank of ferns, or, if surpassed, surpassed only by their own descendants. Polystichum angulare brachiatum, I suspect, was only occasionally brachiate—at all events, as I remember it, it was not brachiate at all, but was a fine symmetrical upstanding variety having the peculiarly toothed and almost cruciate pinnules of the best brachiato-cristatums. A. f.-f. acrocladon was, and is, remarkable not only for its extreme ramosissimum character, but still more for the glistening hair-like processes which spring from its ultimate divisions and which give an indescribable softness to its outline.

The year 1861 saw the discovery of Talbot's Polystichum angulare grandiceps (still perhaps the neatest grandiceps form of angulare); Polypodium vulgare pulcherrimum, Addison—a rival to omnilacerum and Cambricum; Scolopendrium vulgare crispum Drummondiæ, another fimbriate crispum, and interesting as having in after years served, in Mr. Druery's skilful hands, to demonstrate the analogy (first suggested by Colonel Jones) between the fimbriate crispums and the pulcherrimum varieties of Polystichum angulare by producing aposporous offspring. I am firmly convinced that any of the other truly fimbriate crispums would do the same thing under favourable conditions. Other ferns of this year were Athyrium filix-fœmina cruciatum, Pritchard; Lastrea filix-mas Barnesi; and last but not least, A. f.-f. Victoriæ.

In 1862 came Mapplebeck's Polystichum angulare acrocladon, a remarkable form long supposed to be barren, and which has never yet been proved to be otherwise. The analagous case of A. f.-f. acrocladon, however, indicates a hope that its sterility may one day be broken by care and skill, as in the case of its analogue in Athyrium f.-f. The same year saw Padley's Vale of Avoca Polystichum angulare polydactylum, the first of that race afterwards developed by Colonel Jones, and upon which some of us think he wasted so much skill and energy. Blechnum spicant lineare Barnes, and Lastrea filix-mas grandiceps (found on Warton Crag) were worthy northern finds. In this year Mr. Moly found his first angulare pulcherrimum, though the first had been found a few years before by C. Jackson. Mr. Moly has been by far the most successful finder of these wonderful forms, having found probably a greater number than all other hunters combined. Mr. Jackson Mr. Wills, Rev. C. Padley, and his sister, Mrs. Thompson, are the only others, so far as I know, who have succeeded in finding pulcherrimums, and they have each found one only. These beautiful and wonderful forms are most provoking things to grow—indeed, I have found their cultivation too exciting to be healthy. They are full of surprises, and the surprises are often disappointments. Most of them are intermittent in character. Colonel Jones grew a plant of Mrs. Thompson's pulcherrimum for ten years before he got a characteristic frond, and then he was rewarded by a frond of rare and wonderful beauty. I have a plant of the same, which is at present a perfectly normal angulare, but which may any year give two or three pinnæ of true character just to show that it has not forgotten. Wills found one which remained constant for years, and which is a great beauty; when in character, however, it is a bad grower, and if by any chance you get it to do well the probability is that it will cruelly jilt you by dropping its character like a mask and reverting to practically normal angulare. I have in my garden a plant which was perfectly true last year, and which still has the true fronds of last year green upon it. A strong and vigorous crown last autumn raised my hopes high. Judge then of my disappointment when the fronds came up this spring plain angulare! Once fallen from grace, as it were, this variety, in my experience, never returns to its duty—once a renegade it is always a renegade. The most generally satisfactory pulcherrimum I have seen is a green one of Moly's, which, though always producing some normal fronds, always produces with them a certain proportion of true pulcherrimum character, which is thus always more or less in evidence. Another of Mr. Moly's finds which I have is his variegated pulcherrimum. It is a marvellous thing when at its best as a young plant. It never produces any normal fronds, but is always pulcherrimum. The combination of rich green in its pinnæ with various shades of yellow from pale lemon to deep orange, is a study in colour not to be forgotten. As I said before, when a young plant, with fronds, say, a foot long, it is perfect and altogether lovely. But, alas! when it loses the innocence of youth it develops traits of wickedness, which suggests that there is a good deal of human nature in its composition. Even then, however. it seems to start each new year with good intentions: the first eight or nine pair of pinnæ on each frond will be symmetrical and beautiful, but, as the fronds continue to unfurl, we find that the upper pinnæ are more or less contracted, depauperate, irregular, and—it must be said—ragged. It is thus a combination of all that is best with all that is worst in fern nature. Who shall deliver it from this burden of sin?—eliminating the bad while preserving the good? That is the task which I have set myself, gentlemen, and I do not mean to give it up so long as I can keep the fern alive and so long as I keep life myself. Pardon this long digression on my special hobby of pulcherrimums; I will now resume my discourse.

In 1863 Mr. Barnes found his Athyrium filix-fœmina plumosum and his Scolopendrium vulgare semilacerum robustum; J. Hartley his acutilobe angulare; and Mr. Bolton his Scolopendrium vulgare ramo-digitatum—not a bad contingent from the north; my grandfather found his two forms of Asplenium trichomanes incisum in Co. Clare, and Mrs. Thompson found her Polystichum angulare pulcherrimum. The year 1864 produced P. a. tripinatum Gillett—a noble form only to be thoroughly appreciated when seen grown to its full size in the open air in the south-west. Wright's Lastrea paleacea ramosissima, Scol. v. spirale Barnes, and Lastrea filix-mas crispata Hodgson were other notable finds; while some good new forms were raised from spores, of which may be mentioned Athryrium filix-fœmina splendens by Barnes, and A. f.-f. glomeratum, of Ivery.

Another memorable year was 1865, it having seen the discovery of the two forms of Asplenium adiantum-nigrum grandiceps, A. marinum imbricatum, Scolopendrium vulgare grandiceps John Cousins, S. v. undulato-supralineatum Jones, Lastrea propinqua gracilis, of Forster; L. montana Barnesi, Polystichum aculeatum cristato-gracile Bolton, and many others. Of these the first place must be given to Mr. Barnes's montana, which can well be done without placing any slight upon the host of other good things. At that time Barnesi was an absolutely unique fern, and I well remember the delight and admiration with which I first looked upon it, a magnificent plant two feet high, in Mr. Barnes's garden. This was several years after it was found, I think about a quarter of a century ago. Whitwell and Westlake have since then found fine forms similar to Barnesi in outline, but I believe neither of them has, at all events to the same extent, that peculiar horizontal setting of the pinnæ which made Mr. Barnes compare his plant to "a perfect ladder of the fairies."

The great find of 1866 was Polystichum angulare plumosum Patey, better known as Pateyi, a noble and magnificent fern, which was long stigmatised as barren, but which has to my knowledge several times produced spores, and of which at least one seedling has been raised by Mr. Cropper. This grand fern has the one fault, if fault it be, of being rather particular about its atmosphere and conditions. It is only in the hands of skilful cultivators, who are also favoured with a moist and genial atmosphere (*e.g.*, such men as Bolton, Tyldsley, Cropper, and Moly), that it is really in its best form. Other good things of the year were Colonel Jones's Scolopendrium vulgare crispum robustum, Athyrium filix-fœmina Girdlestonei (another stiff problem to cultivators), Athyrium filix-fœmina proteum, of Clapham, Lastrea paleacea crispa gracilis, and crispa cristata of Lyell. The sensation of 1867 was Polypodium vulgare Cornubiense, found, as so many good things have been found, by a comparatively ignorant man, but brought out and introduced to the world by others who have received perhaps sometimes more than their share of credit. This wonderful fern, as you all know, is not without its bad habits.

Several partially successful attempts have been made to eliminate these irregularities, first by simple selection, in the case of Messrs. Backhouse's trichomanoides, and afterwards by raising and selecting seedlings as in Cornubiense Fowler, and Cornubiense foliosum, of Clapham. None of them can be said, however, to have been perfectly successful, and a true, constant, and perfect elegantissimum still remains a desideratum.

(To be continued.)

THE INFLUENCE OF HORTICULTURE.

MOST people will agree that every human being is more or less affected by society and surroundings independently of the individual atmosphere they create for themselves. And as with the individual so with the community generally. This principle may be termed influence. There are many such, always have been, and are now at work in the world. For instance, there are the different influences of town and country; the influences of music, poetry, and painting; the mighty influence of evil, and best of all, the still mightier influence of good.

Our present purpose is to try and state as shortly as possible the more important of the influences of horticulture, using the word in its usually accepted sense, viz., the cultivation of fruits, flowers, and vegetables. Horticulture, as it is the oldest, has always been described—and is—one of the purest, healthiest, and refining pursuits anyone can engage in. In a word it is the "gentle art." Perhaps I may be allowed to cite an instance or two of the influence of horticulture on the individual. The case of Dr. Carey, the celebrated missionary, is one of the most striking. His garden was one of the finest in India, containing some three thousand species of plants. Writing home to a friend who had sent him some bulbs and seeds, he says, "To make sure that nothing of your valuable present should be lost, I shook the bag over a patch of earth in a shady place, and to my inexpressible delight a plant of Bellis perennis of our English pastures sprang up. I do not know that I ever enjoyed a simple pleasure so exquisite as the sight of this English daisy afforded me, not having seen one for thirty years, and not expecting to see one again." Dr. Carey's youthful love for flowers and plants ripened into a "ruling passion strong in death." When in his last illness, he said to Dr. Marshman, "Ah! Brother Marshman, I have been thinking when I die you will let the cows into my garden." A striking instance, surely, of the influence of horticulture on the individual.

Emerson tells us "it is simply pitiful the things by which we call ourselves rich or poor. Why, I have returned from my morning's walk feeling richer in the possession of a handful of honeysuckle than if I had found a purse of sovereigns by the wayside." The late Mr. Wm. Thomson, of Clovenfords, I believe, publicly stated—amidst the cheers of his audience—that an Edinburgh city clergyman declared when visiting the densely-crowded parts of his parish he invariably received a kindly welcome from the inmates, wherever a few window plants were cultivated, reminding us of Ruskin's splendid sentence—"Flowers are the treasure of the cottager, and in the crowded towns mark, as with a fragment of rainbow, the windows of the workers in whose hearts rests the covenant of peace."

In order that horticulture may have a direct influence agencies must be at work, and in the very forefront I have no hesitation in placing the horticultural press. As the daily press helps to form and guide public opinion in the political world, so it is simply incalculable the influence of the horticultural press in the gardening world, whether as professionals, amateurs, or cottagers. A very eminent gardener once said, "I like to get at the bottom of things, and the horticultural press helps me greatly." Publications, mutual improvement societies, and lectures delivered in different parts of the country by competent persons, are most useful in educating the public mind in the science of horticulture.

Our public parks and botanical gardens, especially our National Garden at Kew which draws its thousands on bank-holidays, and other times, afford a striking example of the influence of horticulture on the community. What can be more healthful and reinvigorating to the toiling masses of London than enjoying the beautiful grounds at Kew, walking in the houses and looking upon tropical vegetation? The noble palms, many of them possessing an interest and value, from an economic point of view, little dreamt of. But perhaps it is through horticultural societies that the influence of horticulture is most clearly seen at the present time; and here I wish to do justice and give honour to whom honour is due, viz., to the Royal Horticultural Society. When constituted, and many years after, it gave an impetus to horticulture in this country totally unknown before. Horticultural societies and the masses act and react on each other in a striking manner. The former—springing up in all directions—could not long exist without the support of the middle and working classes. The societies, by their practice of giving prizes for the best garden produce, create a healthy rivalry among working men, consequently more time and industry is spent on the garden, yielding the happy return of more abundant produce of superior quality, not only for the exhibition table, but for the support of themselves and families. This is the very thing wanted, and we want more of it. Local horticultural societies create a most beneficial influence; the very school children are interested and influenced in a remarkable way. How they clamour for their entry cards on a show morning!

To fully understand the influence of horticulture on the working classes in an ideal way, one must go where they are provided with gardens sufficiently large to grow their own fruit, flowers and vegetables. I have heard it repeatedly said garden produce can always be bought cheaper than grown. Supposing the statement to be true, there is one thing cannot be bought, and that is true quality. Garden produce carted to a wholesale market, recarted to the greengrocer's shop and retailed, cannot compare for a moment with produce fresh from the garden. The vegetables one gets in the average London chop-house are tough and even bitter. The jams and preserves manufactured by the great firms cannot compare with those from the owner of a cottage garden, at least, that is the writer's experience. It is of the most vital importance then, that the masses of working people should have the chance to practise horticulture, whether in garden, or allotment, and there need be no fear but the influences will be all for good.

In Oxfordshire, where apricots do well, many working men pay their annual rent from the produce of a tree on the end of their house. The present Dean of Rochester has, I think, stated, that sooner than lose a crop, the allotment-holders about Nottingham have used the blankets off their beds to protect the blossoms of their fruit trees. An extreme case, no doubt, but it shows what enthusiasm will do when people come under the influence of horticulture.

If horticultural produce is a necessity to the rich, I hold it is much more, from every point of view, a necessity to the working poor. And what can be more satisfactory than the working classes enjoying their meals with plenty of tender, delicious vegetables, luscious fruis, and feasting their eyes on beautiful, if common, flowers, all of their own production, which gives considerably more enjoyment to the producers. As far as I know, this is one of the best results of the influence of horticulture.

S.

EXHIBITIONS AND MEETINGS.

CONVERSAZIONE OF THE SCOTTISH HORTICULTURAL ASSOCIATION.

A VERY pleasant meeting of this rapidly-growing society was held in the fine chess-room of the Royal Hotel, Edinburgh, when about a hundred and fifty ladies and gentlemen accepted the invitation of the president, Mr. Todd, for the purpose of allocating the profits—£250—resulting from the recent great chrysanthemum show in the Waverley Market. Among those present were the Lord Provost, Baillies Shenlock, Anderson, and Hay-Mackenzie, Councillor Cranston, Mr. D. P. Laird, Mrs. Laird, Mr. and Mrs. McIntyre, The Glen, Innerleithen; Mr. and Mrs. D. Mitchell, Mr. John Mitchell, Mr. R. W. D. Murray, Mr. G. G. Moncur, Mr. and Mrs. Loney, Mr. Dunn, Mr. and Mrs. D. T. Fish, Mr. and Mrs. Harrow, Mr. Laird (the secretary), and many others.

Mr. and Mrs. Todd received their guests with much cordiality. Briefly referring to the use and progress of the chrysanthemum show, Mr. Todd gave great credit to the Lord Provost and Town Council of Edinburgh for the use of the Waverley Market, which had been called the finest site for a flower show in Europe, for the liberal prizes, and for their constant patronage and support. It was, therefore, with special pleasure that he was about to ask their treasurer to hand to the Lord Provost a cheque for £100 for the Royal Pavilion scheme of the Royal Hospital. The Lord Provost, in gratefully and gracefully accepting the handsome gift to the city, told the association that in their recent show they had done three good things. They had stimulated an interest in the beautiful chrysanthemum, they had given a vast deal of pleasure to the citizens of Edinburgh, and by handing over these cheques they had placed the city under a debt of gratitude to the society. On behalf of the Royal Infirmary he thanked them most heartily for that handsome cheque, and he was sure that his colleagues would be very grateful when he reported it to them. Mr. Cook gratefully accepted the cheque for £50 on behalf of the Sick Children's Hospital, as it would prove a great encouragement to the committee amid a good many financial difficulties.

The next speaker, Mr. D. Mitchell, in proposing the health of "The Lord Provost," showed how good deeds repeat themselves, stating that the oldest horticultural society in Scotland, the Royal Caledonian, has also determined to give £50 to charitable purposes. While writing these lines, and taking part in these kindly charities, we hear that one or more venerable societies, Perth, to wit, is languishing for lack of funds. Could not such devote a portion of their next gains to charitable objects. For there are among men and institutions that giveth and yet increase, and there are that withholdeth more than is meet, and it tendeth to poverty. As stated last week, the Scottish Horticultural Association has given cheques of £50 each to the Gardeners' Benevolent Institution and the Gardeners' Orphan Fund. Who among our richer societies will do likewise?

A delightful evening was spent in speech, song, recitation, conversation, &c., and concluded with votes of thanks to Mr. and Mrs. Todd, "Auld Lang Syne," and God Save the Queen. D. T. F.

READING GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

The last fortnightly meeting for the season 1897 of the above association was held the other evening in the Abbey Hall (by kind permission of Messrs. Sutton and Sons), and was presided over by the president (Mr. C. B. Stevens.) A very large number of members attended to hear a paper entitled "A Chat about Chrysanthemums" by Mr. H. J. Jones, of Lewisham. The paper was given in a very interesting manner, and was full of practical hints and illustrations, and was greatly appreciated. The paper was divided under several headings, such as propagation, composts, potting, manuring, watering, insects, housing, exhibiting, &c., and without doubt many were benefited by the wrinkles given. A splendid exhibit of flowers by the members greatly added to the interest of the meeting. Messrs. Sutton and Sons sent some beautiful specimens of cyclamen, including Sutton's Salmon Queen, Vulcan, White Butterfly, &c.; Mr. Townsend, Sandhurst Lodge Gardens, staged some grand plants of Primula obconica; Mr. Bright sent dwarf plants of W. H. Lincoln chrysanthemum, showing the decorative value of plants grown in three-inch pots; Mr. Bradley, Tilehurst Nurseries, exhibited cut blooms of chrysanthemums and a basket of mushrooms; and Mr. Woolford, The Gardens, East Thorpe, exhibited a splendid specimen of begonia Gloire de Lorraine.

OBITUARY.

MR. JAMES BROWN, gardener for over forty years at Abercairny, Perthshire, the splendid domain of Captain Moray, died, we regret to learn, on December 22 last. Mr. Brown was for many years a keen and most successful competitor in the classes for vegetables and hardy fruits. At Perth, Dundee, Edinburgh, and Glasgow his skill as a cultivator was strikingly exemplified. Mr. Brown's services as a judge at the leading shows was much in request, and by reason of his knowledge and conscientious adjudication he commanded the respect and confidence of exhibitors. His work in the fine gardens under his charge, and devotion to his employer's interests, were duly appreciated by the gallant Captain, who, like generations of his forbears, is highly esteemed as employer and proprietor.

Christmas Grapes.—I was rather surprised to find when, a day or two before Christmas, visiting one of our market grape growing establishments, where there was hanging a fine lot of well-coloured Muscat of Alexandria, that only blacks, such as Alicante and Gros Colmar, were being cut for market. When I referred to this the grower handed me a telegram he had received from his salesman requesting that no more Muscats be sent until after Christmas, but wanting more blacks. "We have had a good week for blacks," said the grower, and so it seemed, when I learned of the large number of baskets that had been sent to London. The price now is not a great one, but it is a paying one, and that satisfies. As to the now hanging Muscats they will fetch a shilling per pound more in January than they have done at Christmas, and because of that the grower is content to let them hang. Grown in soil of moderate quality and texture but well fed from the surface, the berries are fine and plump, as also well coloured, so that they will hang well for a few weeks longer yet. Clearly we have no white grape, old or new, that can equal Muscat of Alexandria as a late one. It is presumed that the average Christmas purchaser of grapes is not of the wealthiest, or possessing the most refined taste. Muscats are a little above his price, and blacks look on the table so much more imposing. When the best class dinner parties are on, then the Muscats will be required. Evidently market grape culture is not yet in a bad way.—A. D.

WORK FOR THE WEEK.

WARM ORCHIDS.

AT this time of the year it is best to leave the potting alone, and devote the whole time to making everywhere sweet and clean. Wash the houses well with hot water and soft soap; then sponge every plant, and I am sure even from the point of appearance they will repay for the trouble. It is a great wonder orchid lovers do not grow phalænopsis more extensively, for they are among the most beautiful of flowers. They are now throwing up their spikes, and require to be watched closely. Slugs rather enjoy the taste of a nice young spike. Fog plays havoc with the buds and flowers, so keep up a few degrees more heat to drive it out. Cockroaches want keeping down, and I find Magic paste to be the best thing for them; in fact, no one nowadays should be troubled very much with anything, as we have so many good remedies to fight the battle with. Thrips and red spider trouble us a great deal, and for the destruction of these pests we have XL All vaporizer. Ventilation at this season of the year must be carefully studied. I advocate bottom air at all times, unless the frosty winds are exceptionally cold, and blowing directly on to the ventilators. Do not give too much moisture, as this without sufficient air creates spot; in fact, keep the plants just sufficiently moist enough to develop their flowers; balance the atmospheric conditions by throwing water underneath the pipes, but be careful about throwing any on the pipes, as steam will do harm. The temperature at this time of the year must be carefully considered. One day we are firing hard, and the next very little is required, but the less fire-heat we can do with the better, though I do not like our phalænopsis to have less than 65 degrees of heat at night; still, on some occasions a few degrees lower will do no harm. The warm varieties of cypripediums will do well with the same temperature; in fact, this class nowadays have been so worked on by the hybridiser that one can hardly tell whether they are to be grown warm or cool. Some grow certain varieties as cool orchids, while others treat them as warm ones, and you will find them doing well either way; and, again, others fail to grow them well which ever way they adopt. Selenspediums require a warmer temperature, and the watering of this section should be done very cautiously, or rotting off at the bottom of the growths will result. This also very often occurs when they are grown too cold and wet. A good plan when this failing is observed is to slit the leaf at the top in the middle and tear it clean away, rubbing a little flowers of sulphur over the decayed part. The C. caudatum hybrids and varieties occasionally fall a victim to this rotting, and a careful watch over them is necessary. Very often in large collections, when there is so much to examine, something becomes neglected for a short time and then mischief is done by thrips, consequently it is well to fumigate with X L All occasionally whether thrips are noticed or not. Hybrids of C. bellatulum are very apt to be troubled with thrips, especially such varieties as C. Charles Richman, C. Schofieldiana, C. Chapmani, and C. Chapmani magnificum and others of this class; these are all best grown at the warm end of the cypripedium house, where they require to be very carefully watered and afforded a free circulation of air when circumstances will allow.

Dendrobiums will require plenty of fresh air, top and bottom, with the latter ventilators open night and day; this is supposing the plants are in a resting state. There are many orchidists now who grow dendrobiums in warmth winter and summer in order to obtain a stock, and this may be quite correct for the end in view, but we cannot expect flowers without a period of rest. The flowers of many dendrobiums will be advancing now, so if an early display is required a few may be placed in a few degrees more of heat and brought on gradually, as this is far better than exciting them, and the flowers will be better. A nice display can be kept up at all times of the year with a little forethought, and if the orchids are intermixed with a few adiantums and foliage plants they make a fine show even in the coldest months. The temperatures now should be: Phalænopsis house, night 65 degrees and day 70 degrees, rising with the sun to 75 degrees; cattleya house, night 58 degrees and day up to 65 degrees, according to weather; Mexican house, a few degrees lower. Keep everything clean, keep a sharp look-out for pests, ventilate as much as possible, and water sparingly.—T. STAFFORD, *Tyntesfield Gardens.*

GREENHOUSE AND CONSERVATORY.

OWING to a mild, bright autumn, some difficulty has been experienced in keeping back the late batch of chrysanthemums and other things either for the production of cut blooms or for arranging in the conservatory. These must be brought on gradually, and in sufficient quantities according to the demand and the convenience available for doing so. Plants of chrysanthemums that have been arranged rather thickly, or which have been standing in dwelling-rooms for some time, are not in a suitable condition to furnish sturdy cuttings just at present. The long, puny shoots should be removed at the time the flower stalks are cut down, and the stools arranged near the glass in a cold frame or a fruit house that is at rest. For producing ordinary bush or decorative plants, the cuttings may be dibbled into shallow boxes filled with sandy soil, but it is best to place a single cutting in a thumb pot if it is intended to grow for exhibition. In most cases the first lot of cuttings will have been taken for this purpose, and daily attention will be necessary to see that they do not suffer for the want of moisture, and, on the other hand, that none of them damp off through keeping a close, muggy atmosphere in the frame. If it can be done without causing the cuttings to flag, a little air should be afforded at all times, which will allow steam to pass off, or the lights should be removed for a short time each morning, and the glass dried before they are replaced. If the cuttings are thoroughly watered when they are put in, and the pots partly plunged in fine ashes or cocoanut-fibre, little watering afterwards will be required until roots have formed, at which stage they can stand more ventilation, and there is little fear of them damping. Place newly-rooted plants in a light position as soon as possible, but not where they are likely to experience a draught, for the first fortnight at least.

Arum lilies, azaleas in variety, all kinds of bulbs, together with autumn-potted plants of lilacs and the like, will form the chief subjects to furnish the conservatory for the next two months. Arums may be had in quantities at this season without the aid of much forcing, if they are rightly managed during the summer. We find them flower early and freely when confined in small pots. In these, too, they prove more useful for decorating than when large ones are used. Copious and frequent waterings, however, is necessary, or they quickly suffer, and the roots will stand fairly strong doses of liquid manure. By keeping the plants fairly cool the foliage remains stout in texture, and they continue to throw up fresh spikes. To succeed these Lilium Harrisi is indispensable, but unless the bulbs are repotted up early in the autumn and the pots are now well filled with roots no attempt should be made to force them. Indeed, they should be brought on gradually until it is seen that the flowers are forming, when more heat can be applied with safety. Azalea mollis and lilacs recently potted up will need plenty of water at the roots when placed in the forcing-pit. Anything approaching dryness after the buds have once commenced to swell will cause many of them to go blind, or what flowers are obtained will be small and ill-formed. As the plants come into flower they should be gradually moved into a drier atmosphere, or the bloom will be pale in colour and soft in texture, and will not last long. For giving a bright display at this season few plants can equal pelargoniums. There are many grand varieties now suitable for winter-flowering, but to have these perfect at this season they must have been properly growing since the cuttings were struck last March. It is surprising what a little water these plants require; indeed, it is one of the secrets in securing abundance of bloom to keep the roots rather dry, and arrange the plants on a shelf in a warm dry house. Too much humidity creates sappy growth and little bloom, whilst moisture in the atmosphere during winter discolours the petals quickly, and they soon fall when cut. Weak liquid manure about twice a week will assist them to build up stout flower trusses.

Bulbs before being placed in the forcing pits should be made quite firm in the pots by pressing the soil around them. It is not unusual for these to be heaved up as the roots form, especially when they are put in thickly. By being made firm and well watered before they are plunged in the forcing bed there is less danger of them suffering for the want of moisture. Continue to ventilate freely late batches of primulas and cinerarias, and fumigate the latter frequently. Keep bedding pelargoniums rather dry, and admit plenty of air when the weather is mild.—R. PARKER, *Goodwood Gardens.*

THE FLOWER GARDEN.

AT the present time there are few flowering subjects in the open borders, the most important at this season being varieties of Helleborus niger. Where the flowers of these are prized for cutting, they should be afforded the protection of a handglass, or some other improvised shelter. Oak branches, to which the leaves still firmly adhere, may be cut and stuck in the ground around the clumps; these form a very good screen if placed thickly, and this somewhat darkened protection causes the flower-stalks to elongate, and the blossoms to be a purer white than when fully exposed, Snowdrops may be similarly treated. In the pleasure-grounds strict cleanliness should be maintained. Where there are many deciduous trees, all leaves should be cleared up and carted away without delay, first raking up the leaves, and afterwards sweeping to leave a perfectly-finished path and lawn. Beech and oak leaves are valuable for mixing with horse droppings for the making of hotbeds, also for rotting down for potting use in the form of leaf-soil, and these should be kept separate from such coarse ones as are from the horse chestnut and similar kinds. While mild weather continues, walks and lawns may receive attention. Where the latter are mossy, which is often the case if the situation be damp and shaded, or the soil very poor, it should be scratched up with a fine-toothed iron rake, and, after sweeping all off cleanly, a top-dressing of fine loamy soil, wood ashes, and soot, should be applied, the two latter to the proportion of about one-fourth of the whole. After mixing thoroughly, spread the dressing thinly over the surface of the lawn, aud brush it well in with new brooms. If the lawn is excessively wet, the finer grasses will not succeed, and in this case the present time will be a suitable one for the work of draining to be carried out. The ordinary earthenware pipes generally in vogue for this purpose may be used, arranging for a proper outfall, and filling in over the pipes with a few inches of rough stones, clinkers, or anything of a like nature; or, failing the pipes, these may be used alone in larger quantities. The drains should be from two to three feet in depth, and run parallel at about thirty feet apart.

In the absence of frost, uneven lawns may be made level, cutting the turves to a convenient size for moving, and stacking them close to the portion to be dealt with. This done, dig over the surface with forks a few inches in depth, adding fresh soil if necessary. After raking quite level, tread down firmly, and carefully relay the turf, and the latter should be beaten down quite firm. Gravel paths may also be taken in hand now. Old paths having a sufficient depth of gravel may be made to look like new if carefully turned two or three inches in depth with flat-tined forks. Paths that require regravelling should first have the surface broken up before applying the new gravel. This kind of work is best done in dry weather. In the flower garden all vacant beds should be dug or trenched, and so prepared to suit the kind of plants with which they are to be filled during the coming season. For pelargoniums the soil should not be made over rich, otherwise a rank, coarse growth will ensue, and very few flowers. Calceolarias and other subjects quickly affected by drought should be placed in heavier and well-manured soil capable of retaining moisture as long as possible. Beds and borders intended to be filled with sub-tropical plants should also be freely manured and deeply dug, as a bold and strong growth is in this case desirable.—C. HERRIN, *Dropmore Gardens.*

HARDY FRUITS.

In notes under this heading I shall in a great measure detail my own practice, and readers of the GARDENERS' MAGAZINE should take into consideration the locality and vary the work, so that in the north some of the advice given may be somewhat in advance of the season; but this will be a gain, as hardy fruit are not always given timely attention, not because there is any desire to delay the work, but from inability to do it owing to scarcity of labour and means. On the other hand, in this department there is much saving of labour by doing work now which, if left till spring, cannot be so well attended to. Hardy fruits deserve notice, for they form one of the best-paying departments in the garden, and one, I am glad to see, has had ample space in these columns of late years. In writing on the merits of fruits, I would also ask readers to note that these vary so greatly in diverse soils that in giving any kinds a trial the soil should be considered; localities also in a measure alter the character of hardy fruits, for in our case most kinds are ripe much earlier than the dates usually given, and our light, gravelly soil being largely answerable. The weather here has not been at all favourable for outside work of late, there having been much fog and frost combined; pruning has been nearly at a standstill, but there is no lack of work needing attention, and the frost promises to be of short duration, so work should not be delayed. This season our pruning is a slow business, as many of the wall trees have their branches close together, and with young trees crowding often happens, as there is at times too much wood left in. To remedy this we have taken down the trees from the walls, lowered the branches, giving more room, and by so doing we shall have finer fruits and cleaner trees. Crowded trees are so difficult to keep clean, and in the case of cherries, figs, peaches, and nectarines, the fruits come smaller and are consequently less valuable for the table. Now is a good time to thin out old spur growth. and in doing this work select those growths farthest from the wall, giving each a clean cut to within an inch or two of the base—the distance must be judged by the wood and position of the spur—and the cut portion will next season push out a new growth close to the wall, which, if stopped in due course, will make fruit spurs in a short time. On the other hand one cannot without injury to the trees remove many spurs at one time, so the work must be done piecemeal. I do not advocate the old plan of laying in all the young wood made by cherries of the Morello type, as crowding is not advantageous, and in our case we spur back the weaker shoots, laying in the stronger, and by so doing get fine fruit on the spurs.

Peaches and nectarines need so little attention from October to February that I need not refer to these trees at length, but I pay more attention to retarding the growths at this season than to giving much shelter when in bloom in a southern locality, for the hardier the trees are grown the better the crop. It is an easy matter at this season to take away from the wall the new growths or small shoots, and so harden the buds that they break much later. Do not, however, unloosen the main shoots or branches as the trees would become broken by winds. Not only does the unnailing harden the wood but it cleanses also, this being equally important. Any pruning of these trees may also be done, but it is the best policy in exposed places to defer pruning till a later period, but the peach and nectarine, with ample attention during the summer, should not need much pruning, especially if the old fruiting wood is removed as soon as the crop is cleared. I would strongly advise any planting of these fruits, also apricots, to be attended to. I prefer planting the fruits named early in the autumn, and though there is a danger of the bark shrivelling, the trees left too late suffer in hot dry seasons. Up to this date there has been no frost to damage newly planted trees, but it is well to cover the soil around them with strong litter. I do not advise decayed matter as if left late in the spring it prevents the sun warming the soil and retards root action. When fruit trees are being pruned it is a good plan in the case of cherries or plums to cleanse also, as though the trees may be clean the walls are not, and there are numerous insects lurking in crevices and these can be reached more readily when the trees are away from the wall. We use quassia extract with sulphur, and it saves us much labour in summer.—G. WYTHES, *Syon Gardens.*

ST. CLARE CASTLE, RYDE, ISLE OF WIGHT.

THIS is the marine residence of A. G. Vernon-Harcourt, Esq., which is beautifully situated in well-wooded grounds, and within a mile of the town of Ryde on the east side. The castle itself is a very ancient structure—which has received several additions from time to time—on a slight eminence with a commanding view of Spithead and the mainland, which is greatly enhanced from the castle tower. The interior of the castle is well fitted up to meet all modern requirements of a nobleman's residence. The gardens, which are under the capable management of Mr. Charles Meehan (who is a brother to Mr. Thomas Meehan, of Germanstown Nurseries, so well known in the botanical and horticultural world), contain many things worthy of note. A fine batch of cinerarias which are timed to be in perfection at Easter are very healthy, with large leathery leaves free from green-fly and the leaf-mining maggot. A large number of Calla æthiopica are just pushing up their spathes. The principal varieties of grapes grown are Gros Maroc, Trebbiano, and Black Hamburgh, which have made some good new wood, that is thoroughly ripened. In the stoves I noticed some fine plants of Pancratium fragrans, Hibiscus Cooperi, Pentas, Eulalia, Cyperus, and Angiopteris evecta. The peach trees under glass have made remarkably fine wood which is well ripened and thoroughly clean, and promise well for another year.

The walled-in garden, which is some two acres in extent, contains some well-trained apricots, pears, and plums, and also some fine healthy bush trees of apples. In the park there are avenues of thorns and rhododendrons (R. ponticum), and several fine trees of Cedrus deodora, Photinia serrulata, Paulownia imperialis, Magnolia grandiflora and American plants of Thuja "George Peabody," and a potentilla. The place is unquestionably worthy of a visit from all lovers of gardens, parks, and woods. Mr. Meehan is not only a keen observer, but an experimentalist, and has this year grown cannas as aquatics; but they have scarcely realised his expectations, and he thinks they will do better not totally submerged in water, but simply with the base just touching the water. My visit and interview was most instructive, for we discussed the questions of canker, gumming, &c.

S. HEATON.

PLUCKING LIVE GEESE.

IT will be a surprise to a great many people who gratified their appetites with the savoury Christmas goose to learn that the practice of plucking geese alive still obtains in some part of the country, especially in Lincolnshire. Divers opinions are entertained with regard to the process. Some persons hold it to be cruel, while others think otherwise. The task is invariably allotted to a man who is known as a goose puller. His mode of procedure is, to say the least, effective. Having caught his goose, he tucks the head of the captured bird under his left arm, and forthwith proceeds to the laying on of hands. The plucking is performed in an expeditious manner, and in a very short time the bird is set free, shorn of feathers on breast, sides, back and top of the wings. The effect is not pleasing to the eye, and detracts from the beauty and symmetry of the bird. Its advantage, however, is said to be that by the time it is ready for the poulterers it has increased 2lb in weight.

The contentions of those who hold the practice to be a reprehensible one are that the plucking causes a good deal of suffering, that considerable pressure has to be exerted to keep the bird in position while the operation is in progress, and the effects of the exposure to the weather after the plucking, to say nothing of the fright to the bird in being caught and subjected to this treatment constitute cruelty. On the other hand, those who have been plucking geese for years by the hundreds and thousands maintain that if the feathers were not plucked they would drop off. They go farther, and say it is an advantage to the bird rather than otherwise, that a goose that has been plucked thrives better than one that has not undergone the process. Again, it would not fetch so much money, the flesh would not be of the same quality, and, as a marketable commodity, it would not be so valuable. There was no cruelty, they argue. The whole process only took about five minutes. An experienced puller reckons that he merely draws his fingers along the body, and that when he does that the whole of the feathers on the breast and back come off.

This conflict of opinion has recently been put to the test. A case has been heard by the Marshland magistrates at Terrington, brought at the instance of the Norfolk and Norwich Society for the Prevention of Cruelty to Animals. The contention of the prosecution was that to pluck geese alive was "unquestionably a barbarous and cruel practice, and could only be sanctioned and carried out by cruel, granite-hearted individuals." The defence, of course, was that it was not cruel, that it was performed with reasonable care and skill, and that, in the result, the flesh of the bird was rendered more fit for human food. The magistrates took this view, and dismissed the case.—*Daily Mail.*

BACKING THE FAVOURITE does not always bring pleasure or profit to those concerned in it. Frequently the horse no one thinks much about wins, and those who gain anything are few and far between. This cannot be said with reference to Holloway's Pills and Ointment, for they never disappoint those who have faith in their merits. With reference to the Ointment medical men are so convinced of its merits that they recommend it to patients as the best remedy within their experience. The Pills, also, have a marvellous effect upon the system; and it can be truly said that whatever the cause of the trouble may be the combined medicines will restore the patient to health.—[ADVT.]

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS MAGAZINE, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Secretaries of horticultural societies are invited to send early notification of forth coming exhibitions and meetings, and are requested to advise us concerning change of dates

Address.—H. N., Deal: The address you need is W. Horne, Perry Hill, Cliffe, Rochester.

Roses under Glass.—J. M. S., Bognor: Three good varieties to suit your requirements would be La France, Beauty of Waltham, and Duke of Edinburgh.

A Garden Nuisance.—P., St. Ives: So far as we can judge from your letter, you have good cause for complaint and sufficient ground for bringing an action against your neighbour to obtain an injunction restraining him from continuing the nuisance. Whether you sue also for damages is a point you will be best able to decide. Sorry we could not answer you in the previous issue.

Hollow Celery.—W. E. W., Leeds: No doubt the failure was due to excessive liquid feeding following a period of drought or during such a period. You can scarcely make the ground too rich for celery, and moisture is absolutely necessary; liquid manure must, however be given with care, or pithy instead of crisp succulent stems will result. The vines may be lifted and potted at once, taking care that subsequently the roots are kept nicely moist; place the vines in a cool house.

Preserving Fungi.—C. G., Hayward's Heath: Fungi may easily be bottled in spirit and thus preserved for reference, but the colour will not be retained by this means. A good mixture for the preservation of colour as well as form consists of eight pints of water mixed with two pints of sulphuric acid; when well mixed, add a pint of creosote, then bottle the specimen in this, and cork as tightly as possible.

The Lindenia.—J. M. S., Bognor: The *Lindenia* is a work devoted almost exclusively to the illustration and description of orchids. The illustrations are coloured, and the text is in the French language. There are six parts to each volume; each part contains, usually, four plates, and one part per month is the rate of issue, though the publication is not very regular. The annual subscription is sixty francs (£2 10s.), and the work is published by M. Lucien Linden, 117, Rue Belliard, Brussels, Belgium.

Brassia Lawrenceana.—F. F., Canterbury: This is a handsome and elegant orchid producing long racemes of spidery flowers, large in size, bright in colour, and sweetly fragrant. It was introduced from Brazil in 1839, and flowered first in Mrs. Lawrence's collection at Ealing Park. The sepals are deep yellow blotched with brown and green; the lip is yellow, with a double keeled white crest dotted with yellow. The species is figured in the GARDENERS' MAGAZINE of May 5, 1894. The variety longissima is a magnificent one, having much longer segments than the type, the sepals in well-grown specimens measuring seven inches in length. The colour is orange-yellow blotched with reddish-purple. The *Botanical Magazine*, t. 5,748, contains a coloured plate of this remarkable form, and a reference to it will speedily dispel any doubts as to the beauty of brassias.

Carpet Bedding.—H. N., Bolton: There is no work in the English language entirely devoted to carpet bedding, but you will find many plans given and plants quoted for designs in McIntosh's "Book of the Garden," published in 1853 by W. Blackwood and Sons. This work you may gain access to in a good public library. A recent work, freely illustrated, and devoted entirely to the subject, has been published in German by Ludwig Möller, Erfurt, Germany. The work is by Karl Götze, and entitled "Album für Teppichgärtnerei und Gruppenbepflanzung." The names of plants are, of course, as usual, and there is, at the commencement of the book, the English rendering of descriptive German words and sentences, so that most of the text can be understood by those not acquainted with Deutsch. You should apply to the publisher for price. The book is quarto size, and contains 252 pages.

Pruning Filberts.—T. H. T., South Hants: The scarcity of filberts often occurs through an insufficiency of catkins, or male flowers; consequently the pruning necessary should be deferred until it is seen whether there will be sufficient male catkins to furnish pollen after using the knife. If there is any doubt as to quantity, do not prune until after the male catkins have faded. In the case of trees with unlimited head room, the only pruning necessary will be such as will ensure all parts of the tree an abundance of light and air. Where space is limited a severer method may be adopted. Excessive vigour in filberts must be checked, or the trees will be gross and unfruitful. This cannot be done by stem-pruning, for this but aggravates the evil; the remedy is to be found in lifting and root-pruning, large specimens being root-pruned on one side one season and the other the next.

Protecting Fruit Trees from Rabbits.—Rex, Ely: There are several methods by which attacks by rabbits and hares upon the bark of young fruit trees may be discounted. In our issue for December 18 last, Mr. J. C. Tallack, who has had considerable experience in this direction, points out that an excellent safeguard, and quite an inexpensive one, either from cost of material or its application, is to cut up old fish netting which has become too rotten for further use in protecting fruits, into strips, and wind these around the stems from the ground upwards to a height out of reach of the vermin. No other protection is needed, as they will not tackle the netting, however rotten it may be. Stockholm tar mixed with cow manure, the latter being of the same consistency as the tar, makes a suitable dressing for parts of tree stems that have been gnawed by these pests. Assafœtida, at the rate of a teaspoonful of the tincture to a pailful of clay worked to the consistency of paint, may be painted on to the tree stems two or three times during the winter; this mixture is so distasteful to hares and rabbits that the trees are preserved from harm.

Why not a National Orchid Society?—E. S., Regent's Park, asks: "How is it that there is not a National Orchid Society? We have our chrysanthemum, rose, dahlia, pansy and viola, carnation, cactus, and other special national horticultural societies, besides general horticultural associations and the Royal Horticultural Society, and it seems hard to be understood why no one has hitherto started a special national society for orchids. There is quite as much interest taken in orchids, and quite as many cultivate them both for pleasure or profit as in the case of other special subjects which now have a society to themselves. A National Orchid Society, if set going, would, I feel sure, meet with support from all quarters." The reason why there is no such body as a National Orchid Society is, we believe, largely due to the fact that since orchids became at all popular the Royal Horticultural Society has devoted special attention to them, so that they receive at least as much recognition as any national society could hope to give. The Orchid Committee of the R.H.S. consists of experts from all parts of the country, amateur, professional, and trade growers, and they make awards with great liberality. An orchid lover joining the R.H.S. obtains all the privileges he could expect from a national society and many additional ones; his exhibits will be judged if new or rare varieties, species, or hybrids, and groups be awarded medals according to their excellence; he has free admission to the fortnightly orchid displays at the Drill Hall, and to the finest orchid show in the world, viz., that at the Temple Gardens each May. In addition to the R.H.S. there is a special orchid society at Manchester instituted last year for the convenience of northerners.

Mildew and Rust on Carnations.—F. C., Appleby: Mr. G. Wythes writes: When advising sulphur liquid for plants infested with mildew and rust, I was thinking of Bentley's Mildew Specific; this is a convenient preparation ready for use, and a sure remedy for fungoid growths. For a small quantity of plants, and cases where the above is not at command, it will be well to adopt the older remedy of sulphur liquid dressings, which we prepare by mixing half a pound of flowers of sulphur with a gallon of tepid water, well mix the whole and dip the plants in the mixture, the latter allowed to remain on the leaves for a time. With the sulphur I have used a small quantity of soluble petroleum at the rate of a wine-glass to the gallon, and have found it a great check to rust if applied before the disease had spread far. I am aware that with plants badly affected the best preparations will fail, and it may be necessary to cut away diseased leaves and dress those partially infested. A dry dressing of sulphur and wood ashes is more used as a surface dressing to prevent the disease; we sprinkle it freely over the standing ground or on stages, the mixture consisting of dry sulphur and newly-burned wood ashes. It is also an excellent plan to dust the plants, when dry, on fine days; or what is better, frequently alter the positions of the pots, but not necessarily moving them from frame to frame. We also hold each plant upside down and cover the under sides of the leaves with the mixture advised. Most growers are aware that is the part of the plant most attacked, and dusting overhead is not greatly beneficial. Not only is arresting the disease essential, but preventing it if possible is far better. In our moist atmosphere we find it necessary to ventilate freely on all favourable occasions; and to allow a free current of air through the frames, we raise the sashes both top and bottom.

The Gypsy Moth.—J. H., Tunbridge Wells: The moth you have received from Germany and submitted to us is the Gypsy Moth (*Porthetria dispar*), a very troublesome pest in countries favourable to its multiplication. Fortunately the conditions that obtain in the United Kingdom are not favourable; but in some European countries it multiplies at a rapid rate, and the caterpillars do an immense amount of damage to both timber and fruit trees by stripping them of their leaves. It is abundant in some parts of the United States, and in Massachusetts it is so abundant as to have necessitated repressive measures on a large scale under the direction of the State authorities. According to a report published by the Board of Agriculture of the State giving particulars of the work that had been accomplished in checking the ravages of the pest the Gypsy Moth was not known in America until 1868, when it was introduced by a French naturalist, who imported it in the course of his experiments with silkworms, and upon some of the moths escaping he announced the fact publicly. This took place at Medford, Massachusetts, and within twelve years from the time of its introduction the moth had become a serious nuisance. Within twenty years it had spread into thirty townships, and gained a foothold in each without attracting public attention. In 1889 and 1890 the Gypsy Moth caterpillars were so plentiful in various districts as to eat off the leaves from all trees in gardens, orchards, shrubberies, and woods. The caterpillars were, indeed, so thick on the trees that it is averred they could be heard eating. They climbed over the fences until they made them quite black. They entered the houses, and were even, it is said, found in "beds when the blankets were turned down." It is considered that if the State had taken no action in this matter the caterpillars would have increased to such an extent that they would have bred a pestilence in the infested localities, as the stench arising from them was nauseating. "The foliage was completely stripped from all the trees, presenting an awful picture of devastation, and promising in a short time to kill every tree and shrub and all vegetation in any region visited by the creatures." In 1891 an Act was passed by the Massachusetts Legislature making provisions for waging war against the moth in a systematic manner, and it is estimated that in the course of the first six weeks of the year nearly 500,000,000 eggs were destroyed. As the moth hibernates in the egg form, the destruction of this enormous number must have greatly checked the pests. Grease banding and spraying with arsenate of lead were found to give good results, but winter dressings for the purpose of destroying the eggs were the most effectual. Insectivorous birds of many kinds eat the caterpillars, but in Massahusetts they do not appear to have been sufficiently numerous to hold the moth in check.

Names of Plants.—J. P., Walton: Cœlogyne fimbriata.

W. W., Watford: Petasites fragrans, also known as Tussilago fragrans. This plant has become naturalised in some parts of the country, but, though common, it is of great use for conservatory decoration during winter, especially by reason of its heliotrope odour.

K. B, Henley: 1, Cestrum elegans; 2, Callistemon speciosus; 3, not recognised, roses are out of character at this season; 4, Polypodium subauriculatum; 5, Pelargonium echinatum; send when in flower or fruit.

F. S., Bletchley: 1, Adiantum cuneatum deflexum; 2, Pilea muscosa; 3, Dichorisandra musaica; 4, Cissus discolor.

N. P. M., Sheffield: 1, Erica hyemalis; 2, Viburnum Tinus; Odontoglossum Rossi aspersum; 4, Masdevallia tovarensis; it is the exception for this species to produce but one flower or a scape, two or three is the rule.

Names of Fruits—M. G., Mitcham: 1, Adams' Pearmain; 2, Blenheim Orange; King of the Pippins.

S. M. T., Chester: 1, Winter Codlin; 2, Tower of Glamis; 3, Minchull Crab; 4, Betty Geeson.

D. H. B., Sunderland: 1, Norfolk Beefing; 2, Golden Harvey; 3, Ribston Pippin; 4, Lamb Abbey Pearmain.

S. N, Bath: 1, Hambledon Deux Ans; 2, Hanwell Souring; 3, Beurre d'Aremberg; 4, Winter Nelis; 5, Glou Morceau.

MARKETS.

Covent Garden.

TRADE is rather quieter after the holidays, although supplies are fairly large and good. Fruits and nuts are most in request, and cut flowers are greatly in demand at moderate prices.

FRUIT.—English apples, 4s. to 9s. per bushel; American and Nova Scotian, 14s. to 35s. per barrel; French pears, 5s. to 8s. per crate; 4s. to 9s. per box; English grapes, 1s. 3d. to 2s. 6d. per lb.; Almeria, 10s. to 20s. per barrel; bananas, 5s. to 10s. per bunch; pineapples, 1s. 6d. to 4s. each; lemons, 8s. to 15s.; oranges, 8s. to 18s.; pomegranates, 7s. to 8s. 6d. per case; tangarines, 8d. to 1s. 6d. per box; Canary tomatos, 10d. to 1s. 6d. per tray; 4s. 6d. to 5s. 6d. per case; dates, 10s. to 12s. per cwt.; French chestnuts, 6s. to 9s.; Italian, 12s. to 14s. per bag.

FLOWERS.—Arums, 4s. to 6s.; carnations, 1s. to 3s.; chrysanthemums, 6d. to 2s. 6d.; gardenias, 3s. to 5s.; eucharis, 4s. to 6s.; Lillium Harrisi, 4s. to 6s.; tea roses, 6d. to 1s.; pink roses, 1s. to 3s.; cattleyas, 6s. to 10s.; Odontoglossum crispum, 2s. to 4s.; and tuberoses, 3d. to 4d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; chrysanthemums, 3s. to 9s.; marguerites, 2s. to 4s.; mignonette, 2s. to 4s.; pelargoniums (scarlet), 5s. to 6s.; and violets, 1s. 6d. to 2s. 6d. per dozen bunches; azaleas, 9d. to 1s. 6d.; stephanotis, 4s. to 6s.; white narciss, 9d. to 2s.; Roman hyacinths, 6d. to 1s.; lily of the valley, 1s. to 2s.; and pelargoniums, 5d. to 9d. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 3s. to 4s. per bunch.

VEGETABLES.—English onions, 5s. to 5s. 6d. per cwt.; Valencia, 5s. 6d. to 6s. per case; horseradish, 12s. to 16s.; sprue, 5s. to 7s.; celery, 9s. to 18s. per dozen rolls; sprouts, 1s. 6d. to 2s. per half-sieve; seakale, 12s. to 18s. per dozen punnets; French lettuce, 1s. 3d. to 1s. 6d.; endive, 1s. 6d. to 1s. 10d.; artichokes, 2s. to 2s. 6d.; cauliflowers, 1s. 6d. to 2s. per dozen; beetroots, 2s. to 3s.; cabbages, 4s. to 6s. per tally; turnips, 2s. 6d. to 3s. 6d.; carrots, 2s. to 3s.; parsley, 1s. 6d. to 2s. per dozen bunches; eschallots, 2s. to 2s. 6d. per 12 lb.; potatos, 55s. to 100s. per ton.

Borough Potato Market.

There is a moderate trade passing at prices recently quoted. Stocks good and supplies light.

Dunbars, 115s. to 125s.; Hebron, 85s. to 105s.; Snowdrops, 85s. to 95s.; Bruce, Maincrops, and Sutton's Regents, 75s. to 85s.; Reading Giants, 75s.; Saxons, 75s. to 80s. per ton; Belgians, 3s. 3d. to 3s. 9d.; Germans, 3s. 9d. to 4s. per bag.

THE WEATHER DURING THE WEEK ENDING DECEMBER 25, 1897.

The mean reading of the Barometer during the week at Greenwich was 30·28 inches, and that of the Thermometer 35°·8, the latter being 2°·9 below the week's average in the 50 years 1841—90. The direction of the wind was easterly, the horizontal movement of the air being 35 per cent. below the week's average in the 16 years 1860—75. The duration of registered bright sunshine in the week was 12·9 hours. The measured rainfall amounted to 0·02 of an inch.

NATIVE GUANO.

BEST AND CHEAPEST MANURE FOR GARDEN USE.

Price **£3 10s.** per ton in bags. Lots under 10 cwt., **4s.** per cwt., 1 cwt. sample bag sent carriage paid to any station in England on receipt of P.O. for **5s.**

Extracts from 22nd annual collection of reports:—

NATIVE GUANO FOR POTATOS, VEGETABLES, &c.

C. H. TINDALL, Bardney: "Used for Potatos. Result very satisfactory; yield much above average. A splendid manure." G. WATTS and SONS, Bournemouth, report: "Good for general purposes. Grand for all Root Crops, Tomatos, and Cucumbers. Find it so cheap; and it does not exhaust the ground like other manures."

NATIVE GUANO FOR FRUIT, ROSES, TOMATOS, &c.

E. F. USHER, Sidcup: "Potatos and carrots, splendid crops; Peaches, Nectarines, &c., splendid. Should not like to be without it on any consideration." G. STONARD, Gardener to Sir A. T. Watson, Bart.: "Used for seven years for Peaches, Grapes, Tomatos, Cucumbers, Roses, and Chrysanthemums with excellent results."

Orders to the **Native Guano Co. (Limited)**, 29, New Bridge Street, Blackfriars, London, where pamphlets of testimonials, &c., may be obtained. Agents Wanted.

EPPS'S selected PEAT.

A SPECIALLY good stock now on hand of ORCHID PEAT in good condition; also for Stove, Greenhouse, and Hardwood Plants, Rhododendrons, &c., in large or small quantities. THREE INSERTIONS FOR THE PRICE OF TWO!
COPIES OF THE "GARDENERS' MAGAZINE," POST FREE, TWO PENCE HALF-PENNY.

A LADY wishes to recommend a LAD of 16, for garden work under a gardener; nearly two years' good character. — Mrs. RICHARDSON, Duston Vicarage, Northampton.

BARR and SONS have on their Register several competent HEAD and UNDER GARDENERS. They will be pleased to furnish full particulars on application.—12 and 13, King Street, Covent Garden, London.

GARDENER (Head).—Wm. Fyfe, Lockinge Gardens, Wantage, would have great pleasure in very highly recommending George Ellwood, foreman here, as a thoroughly trustworthy and practical man.

GARDENER (Head Working); age 34; two children; life experience in first-class establishments; well up in all departments; first-class testimonials.—BEARDSLEY, Grove Cottage, Golder's Green, Hendon.

GARDENER (Head Working, or good Single-handed); married; practical experience in all branches; good references; leaving through no fault; age 36.—Address R. WATERS, The Moat, Soham, Cambs.

GARDENER (Head Working); age 29.—T. FENWICK-HARRISON, Esq., King's Walden Bury, Hitchin, Herts, highly recommends A. Jefferies to any lady or gentleman requiring a trustworthy man; life experience in large establishments, and three and a half years in present place as foreman.

GARDENER.—Experienced, competent for growing nice flowers and vegetables, has many prizes for stove, greenhouse plants, &c.; management of all-round general work as responsible man; age 37; good references.—Write to B., 11, Holmes Road, Kentish Town, N.W.

GARDENER (Head Working).—Situation desired as above; good all-round practical man; married; aged 40; life experience; highest references from the Hon. Mrs. Dudley Pelham; also Mr. W. Drover, Fareham Nurseries, Bedford Norton, St. Lawrence, I.W.

GARDENER (Head Working, or good Single handed); well experienced in all branches; six years' good character; married, age 32.—Address, J. BANKS, 88, Park View Villas, Brighton Road, Reading.

GARDENER.—Advertiser (aged 39, married) now in London neighbourhood, seeks permanent situation; he has a good practical training.—Full particulars sent on application to E. L., care of Dickson's Nurseries, Chester.

GARDENER (Single-handed or otherwiise); age 28; married, no children; 14 years' experience in all branches; good reference.—WALTON, 27, Affleck Street, Pentonville, London.

GARDENER (Single handed or with one under); 10 years' experience Inside and Out; single.—H. TIDBURY, Basildon Park, near Reading, Berks.

GARDENER (Second in private establishment where four or more are kept); Inside preferred; age 23; good character; state wages.—W. UNDERWOOD, 52, Ravenswood Road, Balham.

GARDENER.—Young Man seeks situation to help in garden; good character; single; aged 25. Apply to J. TROWBRIDGE, Highwood Cottages, near Romsey, Hants.

JOURNEYMAN (First, or Foreman in medium establishment).—Inside; good recommendations from last and previous situations; age 24; abstainer.—S. JORDAN, 31, South Grove, Highgate, London, N.

LORD CARLISLE wishes strongly to recommend his Head Gardener (J. Riddell) to anyone requiring the services of a thoroughly practical, scientific, and energetic gardener of proved ability and integrity; exceptional testimonials and references; leaving through reductions. — Address, J. RIDDELL, Castle Howard Gardens, York.

MR. LAURENCE PEEL is anxious to recommend a Youth of 17, who wants to improve his knowledge of Gardening; has been in his service four years; is very active and intelligent.—Address, "AVONSIDE," Fordingbridge, Hants.

REV. H. H. MILES can highly recommend his gardener, who has been upwards of fourteen years in his service; thoroughly understands vines, glass, &c.; leaving in consequence of establishment being broken up.—Address, J. MEIKLEHAM, Dunfield Lodge, Kington, Herefordshire

RICHARD SMITH and CO., beg to announce that they are constantly receiving application from Gardeners seeking Situations, and that they will be able to supply any Lady or Gentleman with particulars, &c.—St. John's Nurseries, Worcester.

WANTED, Situation as GARDENER, single-handed or good second; age 26; eight years' good experience, well up in grape and tomato growing; five years' excellent character.—H. SKINNER, 3, Bay View, Torquay, South Devon.

Herbaceous and Alpine Department.

YOUNG MAN (age 22) with good knowledge of above, would like to take charge of collection of same; private preferred; abstainer; good references.—WILLIAM SHEPPARD, 94, Waverley Place, Gigant Street, Salisbury.

YOUNG MAN (good position), desires situation in nursery; quick, willing; 18s.; references.—STANWELL, Ipsden, Wallingford.

YOUNG MAN (aged 21) seeks re-engagement as UNDER GARDENER; five years' experience; good references given.—F. PRIOR, 36, East Lockinge, Wantage, Berks.

Situations Vacant.

Advertisements under this heading are charged 2s. 6d. for Four lines (32 words), and 6d. per line of eight words after.

A YOUNG MAN, thoroughly capable, all-round and energetic, wanted as GARDENER (¼ acre); fruit, vegetables, and greenhouse; must be able and willing to make himself useful indoors.—Apply by letter, giving full particulars and wages required, JOHN B. LOFTING, Mount St. Mary's, Ealing.

WANTED, Two UNDER GARDENERS, one for Houses, the other for Kitchen Garden; wages 16s. and rooms.—Apply HEAD GARDENER, Heverswood, Brasted, Kent.

IMPORTANT NOTICE.

AN EMPLOYMENT REGISTRY DEPARTMENT IS CONDUCTED IN CONNEXION WITH THE "GARDENERS' MAGAZINE," AND THE CHARGE FOR AN ADVERTISEMENT ***INCLUDES A FREE ENTRY ON THE REGISTER FOR ONE MONTH.*** IF NOT SUITED AT THE END OF THAT TIME, AND IT IS DESIRED THAT A NAME SHOULD REMAIN, IT WILL BE CONTINUED FOR A FURTHER PERIOD UPON RECEIPT OF A REQUEST. IMMEDIATE NOTICE MUST BE GIVEN WHEN AN ENGAGEMENT IS SECURED.

A List of Gardeners on the Register will be supplied upon application to the Publishers if a stamped envelope is forwarded, addressed 148 and 149, Aldersgate Street, London, E.C.

PEARSON'S CHEMICAL MANURE.

(By Parcel Post—it is so large).

CONTENTS.—The Best Seeds and Potatoes for Garden and Farm: also, Descriptive Lists of Carnations, Chrysanthemums, Dahlias Fuchsias, Gladioli, Herbaceous Plants Pansies, Pelargoniums, Pentstemons, Phloxes Pinks, Pyrethrums, Roses, and Violas; *with Full Cultural Directions for each.*

PRESS AND OTHER OPINIONS OF THE BOOK.

WEST HUMBERSTONE.—"Your Catalogue and Guide safe hand. I am very pleased with it, and I am sure every Amat in particular, should have one in his possession, as they are wor 100 times their cost."—T. H.

Leeds Mercury.—"For a useful selection of vegetables an flowers, and a trustworthy guide in the culture of these, it vastly ahead of ordinary catalogues.'

ARBROATH.—"Very many thanks for your valuable Catal and Guide. As an Amateur, I find cultural instructions immense value."—D. A.

Bell's Weekly Messenger.—"Contains elaborate and comple articles on cultivation for exhibition as well as ordinary purpo It is thus far more than a mere catalogue—quite an encyclopæ of farm and garden plants."

YARM.—"Thanks very much for your Catalogue of 1897. I looking through it, I find it is even better than last year's, whi I thought could not be surpassed."—W. C., Gardener to Sir T Richardson, M.P.

THE GARDENERS' MAGAZINE.

SATURDAY, JANUARY 8, 1898.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

NOTICE IS HEREBY GIVEN, that a SPECIAL GENERAL MEETING of the members of the Gardeners' Royal Benevolent Institution will be held at SIMPSON'S, 101, STRAND, in the County of Middlesex, on THURSDAY, the 20th day of JANUARY, 1898, at Ten Minutes to Three p.m., for the purpose of electing Two Trustees to fill the vacancies caused by the death of Robert Hogg, LL D., and the resignation of John Lee. And the FIFTY-NINTH ANNUAL GENERAL MEETING of the members of this Institution will be held, at the same place and on the same date, at Three p.m., to receive the Report of the Committee and the Accounts of the Institution (as audited) for the year 1897; to elect Officers for the year 1898, and other affairs; and also for the purpose of placing nineteen pensioners on the Funds, ten of whom will be recommended to be placed on the pension list without the trouble or expense of an election, in accordance with Rule III. 5, and the remaining nine from an approved list of forty-four candidates will be elected by votes.

The Chair will be taken by Harry J. Veitch, Esq., Treasurer and Chairman of Committee, at Three o'clock.

The Poll will open at Quarter-past Three o'clock and close at Half-past Four o'clock precisely, after which hour no voting papers can be received.

The voting papers have been issued, and any subscriber who has not received a copy is requested to communicate with the Secretary,

50, Parliament Street, S.W. GEORGE J. INGRAM.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at One Shilling per line, the minimum charge being Five Shillings. Advertisement Office, 148 and 149, Aldersgate Street, London, E.C.

NOTES OF THE WEEK.

"ABOLITION OF THE TREBLES."

The classes for trebles have so long formed an important feature of the principal exhibitions of roses that we have no doubt many of our readers will regard with considerable apprehension any suggestion that may be made for their exclusion from the shows of the National Rose Society and other associations. For our own part we should stoutly oppose their removal without other classes that have the promise of rendering the exhibitions more interesting and attractive being substituted for them. For nearly thirty years the treble classes have alone helped to relieve the monotony of the rose show carried out on conventional lines, and it would be little short of a calamity to replace them with collections of single trusses. Happily Mr. George Paul, who proposes in the current issue of the *Rosarians' Year Book* the abolition of the classes in which each variety has to be represented by three blooms, is fully alive to the importance of making the rose show as varied as possible, and he proposes as substitutes for these classes others in which the blooms would be required to be shown with several inches of stem. This fact notwithstanding, we should prefer to see some diminution in the number of classes for single trusses to give room for long-stemmed flowers in bunches, to the abolition of the trebles; but Mr. Paul can not only claim to speak with experience, but with authority, and the question is one that is deserving of the most careful consideration. The treble class, as Mr. Paul points out, was originally projected to allow roses being shown in three stages; a bud, a half-expanded bloom, and a fully-developed flower, so as to furnish to the visitors to the rose shows an object lesson of the variety in its several phases of beauty. Nor has this idea been quite lost sight of by the National Rose Society, for in the authorised rules of judging it is stipulated that each treble shall be judged as a whole. In practice it has come to be regarded as necessary, both by exhibitors and judges, that the three blooms of each variety should be as nearly as possible in the same stage as possible. Consequently, the treble classes in Mr. Paul's opinion, no longer carry out the object for which they were introduced. It is admitted that staging three fine blooms of a variety is evidence that the rose is one that can be depended upon to produce with considerable freedom blooms of high quality; but the trebles are considered by Mr. Paul so trying to stage and so formal that, in his opinion, the time has come when they may be abolished as classes. He suggests that in the creation of new classes to take the place of the trebles that the number of varieties should be reduced and the blooms of each variety increased. With a view to assist in bringing about the change he so much desires, Mr. Paul provided the first prize in the amateurs' class for six varieties, seven blooms of each, to be shown in vases, at the National Rose Society's metropolitan exhibition in July last, and the contributions to this and the corresponding classes for trade constituted one of the most delightful features of that great gathering. Mr. Paul makes many valuable suggestions with regard to the formation of new classes, which should have the most careful attention, for there can be no doubt these "new classes would let the public see the habit, growth, and character of each rose, and judge of its adaptability for decoration. Their introduction would give more scope to the individual skill and taste of the exhibitor. To the younger men it would offer some higher object than to learn the dressing of the individual flowers, whilst entailing no greater expense or trouble upon exhibitors."

CURIOUS CLIMATES.

It is rare indeed that we find a record of very curious climatal conditions accompanied by such a lucid explanation as is afforded in the R. H. S. Journal just issued, in connection with the home of the nepenthes. Mr. F. W. Burbidge, when remarking upon Mr. Harry Veitch's paper on these extraordinary plants, described that region as a mountain ever enveloped in perpetual mist or rain, and in the printed report we find this description accompanied by a diagram showing that this is due to the proximity of a lofty mountain range (13,700 feet) to a tropical plain extending from its foot to the coast, some sixty miles distant. The temperatures of the plain and the mountain-top differ consequently from constant freezing point, or thereabouts, on the summit, to 80 degrees or 90 degrees in the shade on the plain below. The inevitable result of this condition of affairs is a hot and highly rarefied atmosphere, holding a large amount of aqueous vapour in invisible suspension on the plain, and a much heavier, because much colder body of air, above it on the mountain-top and sides. To rectify this unstable equilibrium, the colder air naturally descends and the hot air rises, the two mingling midway. The next result is, of course, a tremendous drop in the saturation or dew points of the warm vapour-laden air, the surplus immediately becoming visible either as fog or rain. In the day time, when the shade temperature of the plain is 80 degrees or 90 degrees, the hot air may hold its own to the extent of forming fog alone, though this is always of the Scotch mist kind at the best, but after sundown, when the uprising column is cooler, there is, to use Mr. Burbidge's words, "every night in the year a deluge of rain," and we can see that in an otherwise equable climate, no other result could be expected. Hence, on one spot on our earth, at any rate, the clouds never roll by, and it is on that precious spot that the splendid forms of pitcher plants exhibited by Mr. Veitch to illustrate his lecture, have been developed to fit their surroundings. Curiously enough we have one spot in England, viz.: Seathwaite, in Cumberland, where some of the lofty hills catch the warm moisture-laden breezes from the Gulf Stream in a somewhat similar fashion, and run up the rainfall to 165 inches per annum, instead of the general average of thirty or forty. The greatest rainfall in the world, however, occurs on the Khasia Hills, about one hundred miles from Calcutta, where Sir Joseph Hooker recorded over 500 inches during a seven months' stay; and here again we have a range of mountains in the proximity of a warm ocean and bringing about the same climatic conditions, though no nepenthes, we believe, have been found in this district as might be expected. Even this record, however, would probably be run very close, or may be eclipsed, by that of the nepenthes belt in Borneo, were the constant Scotch mists and nightly deluges fairly brought to book. Despite Mr. Burbidge's experience of chilly air and soakage to the skin for the whole time of his sojourn within this realm of supersaturation, the spectacle of the various nepenthes at home, to say nothing of the drapery of the trees, with the rare Trichomanes pluma and other filmy ferns, doubtless fully repaid him and his companion, Mr. Peter Veitch, for the risk and trouble.

PREVENTION OF CLUB ROOT.

The disease variously known as anbury, club root, and finger-and-toe annually inflicts such heavy losses upon many gardeners and farmers that the County Councils for Cumberland, Durham, and Northumberland are deserving of much praise for the public spirit they have shown in combining their forces with a view to devise the best means of preventing and checking its ravages. Under the auspices of the councils for the three counties mentioned, a series of experiments have been conducted by Professor Somerville in the garden of the Durham College of Science, and the results obtained are of considerable importance. Professor Somerville, as our pages so well testify, has for several years devoted considerable time and attention to the investigation of the disease, which, as our readers are aware, is caused by a slime fungus, scientifically known as Plasmodiophora brassicæ, and in his more recent experiments he set himself the task of determining with exactitude the means by which the disease is the most readily transmitted from one part of a garden or farm to another. To enable those of our readers who are not conversant with the life history of the fungus, we would state that the fungus attacks cabbages, broccolis, turnips, and other of the brassicas, penetrates the plant at the tips of the fibrils, spreads through the tissues, and produces the malformation and rottenness in the roots so familiar to cultivators. When the fungus has run its course, it breaks up into myriads of spores, which hibernate in the diseased roots or soil, and afford a ready means of distributing the disease over a wide area. Professor Somerville had by his previous experiments proved to demonstration that by spreading soil in which diseased roots had been grown over a perfectly healthy area, it at once became infected, and on repeating them he obtained precisely the same results, and ample confirmation of the correctness of the conclusions at which he had arrived. On this occa sion he set apart four plots for the purpose of dealing with the question of the transmission of the disease through the manure of cattle fed upon diseased turnips. The manure was mixed with ordinary soil in the proportion of one to three, and fifty pounds of the mixture was applied to one plot. The second plot received a similar dressing of manure of animals that had been fed upon sound turnips; the third plot was dressed with manure and soil as in the case of the second plot, with the addition that the refuse from the animals' trough, consisting of bits of diseased roots and soil, were added; and the fourth plot received a dressing similar to that of the first plot, with the addition of lime. The results obtained are of much interest. The percentage of diseased roots grown on the first two plots with manure made from diseased and sound turnips, were exactly the same, indicating that the vitality of the spores of the plasmodiophora is destroyed in their passage through the animal. The plot dressed with manure to which the trough refuse was added, produced seventy-five per cent. of diseased roots, proving that the spores of the fungus may be communicated to healthy land, by permitting the diseased stumps of cabbages, cauliflower, kales, and brassicas of similar character, and diseased roots of turnips to find their way direct to the manure. This is in complete accord with the advice we have so frequently given, when referring to the ravages of the plasmodiophora, and should be constantly kept in mind. The addition of lime to the fourth plot effectually checked the development of the disease, but materially reduced the crop of roots, owing probably by liberating nitrogen. In the other experiments slaked lime appeared to be more efficient than quicklime, and lime from the magnesian limestone was more efficient than from the carboniferous formation. It was also found that gas lime, one year old, was more effectual than the same product in a fresh state.

Paphiopedilum is not the name of some new sea-urchin, nor the title of some microscopic fungus recently discovered; it is the generic title by which, in future, our leading botanists wish us to recognise those orchids hitherto known as tropical cypripediums. The title is not a new one, for Dr. Pfitzer proposed it in 1886, and recently, in the reduced form of Paphiopedium, Mr. R. A. Rolfe, of Kew, has put it forward. Discussing the matter in the *Bot. Mag.* Sir Joseph Hooker states that the true cypripediums are inhabitants of cold and temperate regions, while paphiopedilums are all natives of tropical Asia and Australia. The American species, now fairly well known as selenipediums, are still to be known as such. "In Cypripedium proper," Sir J. Hooker remarks, "the leaves are cauline, thin, and plicate in vernation, the perianth marcescent, and sepals valvate in æstivation; in Paphiopedilum the leaves are radical, coriaceous, and conduplicate in vernation, the perianth deciduous, and sepals imbricate in æstivation, the dorsal enfolding the lateral." Dr. Pfitzer also suggested Ascherson's *cypripedilum* for the popular Linnean cypripedium, but this would make what Linnæus wished to be Venus'-foot orchids, into Venus' or Lady Slipper orchids, as they are popularly but erroneously known. Sir Joseph reminds us that Cypripedium of Linnæus should have been spelled cypripodium to be correct, and suggests that to simplify matters and gain uniformity, the generic terms Cypripodium, Selenipodium, and Paphiopodium might be used if the change referred to becomes desirable.

Shade Trees for African Coffee.—A request for the introduction of seeds of Indian and Singalese shade trees into British Central Africa for the purpose of providing shade for young coffee plantations was referred some time ago to the Foreign Office, and Mr. W. T. Thiselton-Dyer, Director of the Royal Gardens, Kew, was desired to report upon the subject. Subsequently H.M. Commissioner in British Central Africa determined to rigidly enforce the regulations for the prevention of coffee disease, which prohibit the importation of seeds from India and Ceylon, for, as Mr. Thiselton-Dyer reported, the coffee disease was introduced into Fiji through the instrumentality of tea seeds from Ceylon. Notwithstanding the splendid attempts made by Sir William MacGregor to stamp it out, it ultimately completely destroyed the coffee industry, which was the most promising planting enterprise in the Colony. The Germans, by some unknown means, have succeeded in introducing the disease into their African territories. In the face of these facts it would, in Mr. Thiselton Dyer's opinion, be the height of folly to run the smallest risk of introducing the disease into British Central Africa, where its presence would be an irreparable disaster. Knowing the mechanical way in which such work is carried out by native officials in India, he does not think that any stipulation as to locality is of the smallest value. Whatever was stated to the contrary, the first parcel of seed would, in all probability, come from a plantation reeking with disease. The present request is the more unnecessary as, according to a coffee planter in Nyassaland who is well acquainted with coffee cultivation in Ceylon, a local African tree, Albizza fastigiata, is admirably adapted for a shade tree for coffee. If this is not sufficient, the rain tree, or Pithecolobium Saman, might be tried. The seed can be obtained in abundance from Jamaica, and this would be perfectly safe.

Exports of Potatos.—British potatos were formerly exported in large quantities to the United States, but since the introduction of the McKinley tariff the trade in potatos has almost disappeared. As late as 1894 the transatlantic shipments from this country amounted to nearly 850,000 cwt. of the value of £167,000, but last year they had dropped to 1,000 cwt., valued at £143. In 1896 the exports of potatos in the aggregate amounted to 341,000 cwt., of which Spain and the Canaries took nearly 43,000 cwt., while the greater proportion of the remainder were sent to British possessions.

The Pelicans at Kew Gardens are always a source of interest to visitors, by reason of their picturesqueness, their wonderful capacity for food, and the cleverness they display in catching in their huge pouch anything thrown them. Two new specimens have now been added to the establishment, and may frequently be seen on the Palm House Pond.

Spanish Chestnuts.—The nuts of the so-called Spanish chestnut form a considerable proportion of the unenumerated fruits imported during the autumn months, and large supplies are sent us from France and Spain. The French chestnuts are ready for sale earlier than those from other countries, and consequently hold the market at the outset. The bulk of the French crop is exported, and being the first to arrive here the nuts realise a better price, and then the dealers supply themselves from Italy, from which country they import as much as fifty thousand hundredweights annually. The Italians, however, are making efforts to establish a direct trade with England. Their chief difficulty hitherto has been that the nuts are apt to germinate, and thus become unfit for the market. A method of checking this germination is said to have been discovered, and is stated to be carried out in the following way: The nut is soaked for seven or eight days in a tank and well stirred daily, after which it takes about a week to dry again. This seems to sterilise it completely, and in this condition it can be exported satisfactorily. It is a remarkable fact that if a second lot of chestnuts are put in the same water they will be sterilised in about half the time. This season a large quantity of the Italian nuts have been placed on the British market.

Tuberous Growths on Vines.—Mr. S. T. Wright sent to the Scientific Committee some gall-like structures taken from vines in the large vinery at Chiswick. He observes that "many of the old and young rods are similarly malformed at their base. It does not appear to affect the health and vigour of the rods. In all the malformations grubs or maggots are present; but neither moths nor weevils have been seen in the house." Mr. Michael pronounced the grubs to be coleopterous, but they were not likely to have been the cause. Prof. Church undertook to examine them chemically. There was no apparent structure in them beyond a mass of cellular tissue with a corky exterior surface.

Horticultural Club.—Special attention is being paid to the question of fruit culture by the members of the Horticultural Club, and there can hardly be any question that could well be more profitably discussed. At the conversazione following the monthly dinner on Tuesday next, January 11, the subject for discussion is "The Seasons of 1896-97: Their Lessons and Effects on the Fruit Crops and Trees," to be opened by Mr. George Bunyard, V.M.H.

Camoensia maxima, a handsome West African climber, that for so many years defied the efforts of cultivators to induce it to flower, is represented in the current issue of the *Bot. Mag.* by a double-page illustration. The flowers are milk-white, the segments being margined with gold. As our readers have previously been informed, this leguminous plant first flowered in Europe at Mythe Castle, Tewkesbury; in November, 1896, it flowered at Kew, and last autumn, a specimen flowered at the Edinburgh Botanic Gardens; during the recent Christmas week the Kew specimen once again flowered. Other interesting plants figured in the *Bot. Mag.* for January, 1898, are Paphiopedilum Victoria-Mariæ, known to orchid lovers as Cypripedium Victoria-Mariæ; the now popular, plentiful, and beautiful Strobilanthes Dyerianus, a stove plant that gained so much notoriety when shown at the Ghent exhibition of 1893; Lathyrus splendens, a species from South Carolina, with blood-red flowers; and Sievekingia Reichenbachiana, a wonderfully quaint orchid from Equador, discovered by Lehman in 1879; it has golden-yellow flowers, marked with blood-red, but the most peculiar part about them is the hair-like fringing of the petals and labellum.

Hungarian Hardy Fruits.—The cultivation of hardy fruits in Hungary has been so greatly developed of late years that an official inquiry has been instituted with a view to ascertain the number of trees and the number of varieties of the several kinds grown in the kingdom. But in consequence of a rumour having been circulated to the effect that the inquiry was being made for the purpose of taxing the trees, those engaged in the investigation experienced considerable difficulty in verifying the returns furnished them. The statistical details are therefore hardly so trustworthy as could be desired. Subject to this qualification, the number of fruit trees enumerated in Hungary was sixty-five million, of which thirty-two million were plum trees and fourteen million apple and pear trees. In Croatia and Slavonia eight million five hundred thousand plum trees and two million apple and pear trees were scheduled.

Fruit Industry of British Columbia.—According to the report of the Agricultural Department of British Columbia the production of fruit for profit is practicable in the greater part of the sections of the colony. Both large and small settlers are planting orchards, and a considerable proportion of those which have become established are bearing satisfactorily. The greatest difficulties with which cultivators have to contend are the prevalence of insect pests and diseases due to cultivation, and the importation of foreign products, both nursery-stock and fruit. The industry, except in individual cases, has, however, not been carried on with much system or knowledge of fruit growing. Trees have been purchased regardless as to whether they were the best and most suitable varieties, with the result that there is a great mixture of fruits, and not much of first quality. Little attention has been devoted to methods of planting, pruning, and general cultivation, so that existing orchards do not, it is stated, fully represent the capabilities of any district. Lack of railway communication, remoteness of settlers from each other, and the difficulties incident to the proper preparation, planting, and keeping of an orchard, have also prevented the success of the industry, but these difficulties are being gradually obviated or overcome. The efforts of the Fruit Growers' Association have resulted in the diffusion of a better knowledge of the development of the industry in the province, which is expected eventually to become a large producer of fruit.

Gardeners' Royal Benevolent Institution.—The annual friendly supper of the members of this society and their friends will take place at Simpsons, 101, Strand, on Thursday, January 20th, after the annual meeting, when Mr. Arthur W. Sutton, V.M.H., will preside. The Duke of Portland has promised to preside at the sixtieth annual dinner to be held in the course of the coming summer. It is hoped that the dinner will be held in June, but the date is not yet fixed.

An Old Oak.—An interesting discovery has been made at Stockport. During the excavations in the construction of sewage works for the town some workmen came across a massive oak tree, with two immense branches. Professor Boyd Dawkins is of opinion that the tree is one of the giants of prehistoric times, and he says that the tree is certainly 10,000 years old. The Corporation of Stockport are at a loss to know what to do with the gigantic tree, which is supposed to weigh about forty tons, and as it is necessary that it should be removed, a proposal has been made to blow it up with dynamite. This has aroused the indignation of a large section of the inhabitants of the town, and the following petition has been presented to the Corporation: "That there is a valuable tree of old oak at present lying upon and exposed in the gravel on and within their property. That the quality in colour, grain, and solidity is better than any that can be bought in the open market. That for artistic work alone it is greatly to be treasured, for nothing in this country is at present grown which can come up to its dimensions. That it contains within itself sufficient material to make the furniture for any public building or town hall which may be erected for the public benefit within our borough. That it only requires lifting from its bed, which in the opinion of competent geologists may be roughly estimated as 15,000 years of occupation. That private effort has failed to achieve its removal. That its destruction would be a public loss and an artistic calamity. That your representatives in council be and are hereby requested to conserve for the borough this grant of Nature to her sons and daughters, whose signatures are hereby affixed." The Corporation have reserved their decision, and in the meantime efforts are being made to bring pressure to bear upon the Council to preserve the tree for the benefit of the town and the country.

A New Alder under the name of Alnus tinctoria was sent several years ago to the Arnold Arboretum by Messrs. J. Veitch and Sons, who probably raised it from seeds collected in Japan. In referring to the tree, Professor Sargent states in *Garden and Forest* that he has seen the same tree in Yezo, and the plants raised from seeds which he brought from that island are identical with Veitch's Alnus tinctoria, a name which, although it has been more or less used in gardens, appears to be still unpublished. On the island of Yezo this alder is a shapely tree from fifty to sixty feet in height, with a trunk often two feet in diameter, growing there on low slopes in rich moist ground, usually at some distance from the banks of streams, which are generally occupied in southern Yezo by Alnus japonica. It has been considered by the Japanese botanists Spach's variety hirsuta of Alnus incana, of Manchuria and Siberia, and it is possible that this view is correct, although, for lack of proper material, representing the different species and varieties of Asiatic alders in American herbaria, it is impossible to form a correct idea on this subject. The leaves of this alder, which, until something more is known of the Manchurian species, had, in Professor Sargent's opinion, best be called Alnus tinctoria, are oblong, obtusely wedge-shaped at the base, coarsely doubly serrate, or often incisely lobed above the middle, and clothed below with soft, close, rufous pubescence, which also covers the upper side of the slender midribs and primary veins; they are thin and membranaceous, from four to six inches long and from three and a half to five inches broad, dark green above, pale below, and are borne on stout petioles an inch and a half in length. The buds of the staminate catkins are an inch and a half long and a third of an inch broad, and are borne on stout peduncles from one third to one half of an inch in length. The fruit is half an inch long and about a third of an inch thick, so that the leaves, the buds of the staminate catkins, and the fruits, are much larger than those of any of the European or North American forms of Alnus incana. The stout, somewhat flattened branchlets marked by only occasional pale lenticels and covered during the winter by a glaucous bloom, and the much larger bright purple-red winter buds, appear very distinct from those of Alnus incana. Several of the plants raised from seeds which Professor Sargent brought from Japan in 1892 are now twelve feet high, with perfectly straight stems from five to six inches in diameter at the base, and furnished with well-balanced, vigorous branches. Shapely and handsome now, they look as if they would grow to a large size and prove valuable ornamental trees.

Illuminated Bouquets.—A paragraph is going the "round" of the press to the effect that illuminated bouquets are the latest fad among fashionable people. Natural flowers are said to be almost dispensed with at many of the big dinners, electrically lighted roses, narcissi, carnations, and other flowers being used instead. The flowers used for illumination are said to be clever reproductions of the true blossoms, blown in thinnest coloured crystal, or made in shell porcelain, and mounted on stems of rubber, with green silk foliage. Down the yellow stem of every flower runs a wire that communicates with a minute bulb in the flowers' hearts, whence flashes forth the electric light. The penny-a-liner proceeds, "Many of these imitation flowers are so beautifully made and perfumed that, when not alight, they are easily mistaken for real flowers," but he fails to add who the persons are that are so ignorant of natural flowers as to mistake glass or porcelain manufactures for them.

Potato, Sutton's Satisfaction.—In the report of the Birmingham Potato Show our reporter stated that in the class for the most handsome dish of potatos the winning variety was Up-to-date, but we learn from Messrs. Sutton and Sons that the variety obtaining this distinction was Sutton's Satisfaction.

Seed Exports.—Garden and farm seeds are shipped in large quantities to the Continent and Australasia, the average annual outward consignments in 1894-96 amounted to over 12,000 tons, of the value of £275,000.

THE BLUE CHRYSANTHEMUM.

Could we but raise a blue chrysanthemum some of our chrysanthemum enthusiasts would give almost any sum to possess that treasure. But why has such a product so far baffled all our efforts in this direction?

First, let us see how a natural cross is effected in the chrysanthemum. The chrysanthemum belongs to the natural order Compositæ or the Daisy family, and to the uninitiated appears at first sight to be a single simple flower, but on closer examination, it is found to be a collection of flowers, crowded together into one head. Two kinds of flowers are usually found to compose these heads in most composites. An outer whorl, usually having a long strap-shaped corolla, and the inner flowers, with regular tubular corolla. In these latter the five petals are joined, and so forms a beautiful little tube. On the inner side of these petals is found another little tube formed of five anthers, cohering at their edges, each being connected with the outer tube by an almost microscopic filament. These anthers bears the pollen grains. Occupying the centre of the flower is the little round ovary with a perpendicular outgrowth, the style, which when opened out at the top in a forked manner forms a bifid stigma. Before a seed can be formed some pollen grains must be transferred from the anthers to the stigma, where, if the conditions are favourable they will germinate, sending out a pollen tube, which penetrates the conducting tissue of the style and reaches down to the ovule, contained in the ovary. The contents of the pollen grain then pass through the tube and fertilisation is effected, the result after further complicated and exceedingly interesting changes, being a structure we term the seed. Some flowers are dichogamous, that is, the pollen and stigma attain their functional activities at different times; this is so with the chrysanthemum, and like the rest of its family it is what is known as protandrous, which simply means that the pollen arrives at maturity and is shed before the stigma of the same flower is capable of receiving it. When the pollen grains of the chrysanthemum flowers arrive at maturity the style is very short, concealed as it were, below the little tube of anthers. A very remarkable and interesting process then takes place, the style and stigma actually dispersing the pollen; instead of using it itself the style commences to grow, and rapidly pushes itself through the little tube of anthers, and taking a number of the ripe pollen grains with it, and causing them to be scattered on the fully matured stigmas of older surrounding flowers.

The brilliant pigments of flowers usually reside in the specialised organs known as petals, though they may sometimes be found in other parts of the flower. These colours, which are of various hues and tints, are—purple and blue excepted—found in the ordinary foliage leaves of some plants, and the colours of petals are in many cases exactly the same as in those foliage leaves from which the green has disappeared. The different hues of flowers are, as it were, laid up in the tissues of the plant. But, as they develop, do the changes in the colour follow any definite or progressive order? Do they run from any one colour to another? We often see progression in the direction of a colour change in the life-history of some individual flowers. One of our wallflowers (*Cheiranthus chæmœlas*) has a yellow flower which changes into red and to violet. One of the forget-me-nots (*Myosotis versicolor*) is pale yellow when it first opens, but changes to faint red, and ends by being blue. The bracts of Hakea Victoria, a greenhouse evergreen shrub, are yellowish-white in the centre the first year, a rich golden-yellow the second year, rich orange the third year, and the fourth year the colour is blood-red. The Virginian stock of our gardens opens a pale yellowish-green, then becomes deeply red, and finally purple and blue. In all these and many others the direction of colour change is the same, from yellow through red and purple to blue, and that is as far in the scale as they have reached, thus proving the fact so clearly shown by Mr. Grant Allen and Sir J. Lubbock that blue flowers represent the most highly-developed lines of descent, which have, or whose ancestors have, passed successfully through all the intermediate stages. Then how has this blue colour become fixed in some flowers? The function of the flower is the production of the seed, and to attain that end we see that fertilisation must be effected. Various and numerous are the ways plants adopt to ensure fertilisation; some have adapted themselves to pollination by insects, and as a result have acquired special peculiarities of structure and colour of their petals, as may be readily seen; those flowers which have undergone the most modification have their colours most altered, as we usually find that the simplest flowers—those with regular symmetrical cups like buttercups—are yellow, and such as these can be visited by any simple insect. Those flowers which are modified still more, like the silenes and campions, which have closer cups and whose nectar can only be reached by higher insects, are usually pink or red; and those which are the most highly modified, like the peas, salvias, violets, monkshood, and larkspur, have assumed special shapes to accommodate bees and other honey-seekers, and are invariably purple or blue.

Anyone visiting a garden where a number of flowers are to be seen during the summer months will find that the highest insects repeatedly visit the purple and blue in preference to the more red or yellow flowers, and, as the insects prefer these colours, the flowers of succeeding generations become as a result more purple and blue, the plants catering as it were for the insects.

The structure of the chrysanthemum flower with its mechanical method of pollination, acts as a preventive against this kind of selection, but the equivalent cross is procured, a cross to all intents and purposes adapted to the structure, conditions, and requirements of the individual flowers. But, as we have seen, it is not a selective cross, as the insects select, and hence, in the chrysanthemum, we get little or no specialisation of petal, colour, and odour. In the natural order to which the chrysanthemum belongs, very few species have as yet risen to the stage of producing blue petals. Out of one hundred and fifty-two species enumerated in Britain ninety-three are yellow, and three only are blue, and these are specialised flowers. The chrysanthemum of Nature is, as its name implies, a yellow flower, and none have ever evolved to the stage of blue, and that, perhaps, is why we do not get a blue chrysanthemum in cultivation. It is easy to make chrysanthemums, or any other flowers, vary within their own natural limits and revert to any colour through which they have passed, but where it is difficult is to make them take a step which they have not taken naturally, and so we find that the most developed flowers are the most varying in colour, and we get yellow and red chrysanthemums with their varieties, but no true purple or blue ones. It may be possible to obtain a blue one by selecting and preserving the most purple from the red forms until a type is fixed, and then in the same way selecting the most blue from the purplish kinds; but this is a very slow and tedious process for man, whose life and patience is so short, and who has to substitute a camel hair brush for an insect's proboscis. He is also further handicapped as Nature is largely against him, and it is little wonder he becomes impatient and disgusted with himself, the chrysanthemums, and his results, and so finally gives up in despair. The man of science learns that from the comparative rarity of blue flowers in Nature, those shades which tend toward blue are less frequent than yellow and red shades, and so we find there are difficulties to be surmounted ere we reach the blue chrysanthemum.

East Park, Hull. HENRY KNIGHT.

VEGETABLES FOR EXHIBITION.

LETTUCE.

LETTUCE (*Lactuca sativa*) without doubt forms one of the most important crops of our kitchen garden. It is universally prized as a salad, especially during the hot summer months, and during that season very little skill and attention is required to bring it to perfection. But in many establishments lettuce of some kind is required every day throughout the year, and to keep up a regular supply much care and forethought are necessary, especially in cold, low, and wet situations. Lettuce may be grouped into two classes, the Cabbage and the Cos varieties, and opinions differ as to which is the best. The Cos lettuce, both Brown and White, is much more solid and crisp than the cabbage, and for that reason is more generally preferred. On the other hand, some people have a special liking for the soft, silky forms of the cabbage lettuce. When, however, constant supply is expected, both types should be grown.

Lettuce will thrive in almost any kind of soil, but to have it in perfection the ground should be deeply dug or trenched, and made rich with good farmyard manure. The first sowings should be made early in February in shallow boxes, of both Cos and Cabbage kinds, and raised under glass. Very little artificial heat is required to raise the plants, a cold frame, providing the frost is kept out, will be sufficient. But the most suitable place at this season is an early vinery or peach house just being started. As soon as the plants are big enough to handle they should be pricked out three inches apart into another box in a light sandy compost. They should be kept as near the glass as possible, and air must be admitted as the weather will permit, to keep the plants from becoming drawn and weakly. Gradually harden the seedlings off, and select a warm sheltered spot in which to plant out as soon as the weather is favourable. The Cos varieties should be allowed a distance of one foot apart each way, and the cabbage kind nine inches apart between the plants and ten inches from row to row. This distance should always be allowed, as nothing is gained by overcrowding the plants. Sowings should be made every ten days during spring and summer, and treated in the same way. By the end of March outside sowings should be commenced, and the earliest sowing should be made on a south border in shallow drills, and the beds thinned, when the plants are large enough, to the distance before advised. A few selections from each thinning should be replanted, as they will just follow the permanent plants, and ensure a constant supply. A capital place for growing good lettuce during summer is on the celery ridges. They will in no way interfere with the celery crop, and the lettuce being somewhat raised, plenty of light and air will reach them, and the best results will ensue.

Small sowings of suitable varieties should be made during September and October in skeleton frames, when protection of some kind can be readily afforded them in severe weather. These sowings will prove of great value during winter and spring, and the smallest plants will generally stand the severest weather if suitable kinds are selected. To meet the demands, when winter salads are required, it will be necessary to give protection to some of the later sowings by planting them in cold frames, or late, light, peach cases. They may be planted closer together than advised for outside planting to economise the space, but at the same time overcrowding must be avoided, or during severe weather, when the lights require to be kept closed, or damp will play sad havoc with them. Should the supply by any means be found to be running short during winter sow some of the forcing kinds in heat, and prick out the seedlings three inches apart, and grow in a gentle heat as near the glass as possible. These will prove invaluable, and should be cut off like mustard and cress; one or two kinds I have tried answer especially well to the treatment. The later sowing, wintered in cold frames or otherwise, should be planted out very early in spring in the most sheltered and warmest spot available, as soon as the weather is in the least degree favourable, and if this is done no break can occur.

Enemies to the lettuce are not very numerous, the most troublesome at all seasons of the year, especially in showery weather, are slugs, and when these are very numerous means must be taken to keep them from ravaging the crop. There is nothing more distasteful to slugs than finely sifted coal ashes, and during showery weather these are not washed away like soot and lime, which are often advised to be used for the purpose. Small birds are sometimes troublesome, but these are easily kept at bay by stretching netting over the beds.

Whenever classes are provided for single dishes of vegetables lettuce are generally included, and the prizes are nearly always well contested as regards numbers. But as a rule a large number of the specimens staged are very indifferent, and stand not the least chance of winning. Worthless kinds are frequently met with, and some examples are past their best or not sufficiently developed. To produce really first-class exhibition lettuce something more than ordinary attention is required. The best results will accrue if treated as follows: Narrow trenches should be taken out one foot wide and fifteen inches deep, and the bottom thoroughly broken up with a fork. The trench should be filled to within three inches of the top with half rotten farmyard manure, and the remaining three inches with some of the best of the soil taken out, which should be made as fine as it is possible to make it with the fork. This is best prepared a week or so before sowing the seed. Shallow drills should be made and the seed scattered thinly along it. Just sufficient soil should be drawn over the seed with the rake to bury it, on which should be sprinkled a dusting of coal ashes, and if the soil is dry at the time a good watering must be given with a fine rose watering pot. Small birds are often very troublesome, and when once they commence to take the seed they generally make a clean sweep of it. Pea guards will be found the best protection, being very neat in appearance, easily put on and removed, and most effectual. As soon as the plants show signs of making their second leaf thinning should be commenced, which should only be done partially the first time, leaving the plants about three inches apart. When advanced one size larger thin out to the proper distance, which should be for Cos varieties not less than thirteen inches, and for Cabbage kinds one foot. A few from this thinning should be carefully transplanted in other prepared trenches. As these will follow those in the original rows, and other sowings are made about every ten days, the exhibitor will be pretty certain of having good specimens at almost any date.

All Cos varieties, both brown and white, whether self-folding or not, require to be tied up and blanched. Tying should be done twice, and always when the plants are perfectly dry. The first band should be put on about a fortnight previous to the show date. Use broad pieces of bast, and tie the first loosely round the plant about half way up, so as to check the growth. The second tying should be made a week later nearer the top of the plant, drawing the whole of the leaves tightly together without bruising them. Should the weather be hot and dry, the plants should be mulched with half-decayed horse manure, and kept well supplied with both clear water and liquid manure. In competition, the white Cos varieties, if presented in good condition, will in nearly all cases receive the awards. A perfect lettuce should be full grown, of large size, heavy and solid when handled, and should stand the test of cutting, which is invariably done in close competition, when the hearts should be found quite near the bottom, and the inside leaves thoroughly blanched. Two classes are sometimes scheduled, one for Cos and one for Cabbage lettuce, and this should be more generally encouraged, as the latter kind stands no chance where the Cos kinds are well presented. Cabbage kinds should be large, perfectly solid, and bear cutting open. Lettuce in a collection of vegetables, unless an unusually large number is required, is in my opinion a weak dish, and counts but little; but for a mixed ornamental collection both kinds of lettuce should be staged, and in a collection of salad lettuce should form the first and most prominent item. The number generally required is three of each kind, and they are best lifted late in the evening with a fork. The roots should be thoroughly washed and left on, some damp clean moss being neatly bound round them to keep them fresh and crisp during the next day. When staged, a sprinkle over with water will also be of great assistance. Two should be placed at the bottom and one at the top, and all three should be as nearly alike as possible, with the head towards the front. If the exhibitor has a long way to travel, much care in packing is necessary. The lettuces should be wrapped in soft paper and placed on the top of the vegetable hamper, or the leaves will be much bruised and damaged in transit.

The best Cos kinds I know of for exhibition are: Carter's Giant White Cos, Sutton's Superb White Cos, Sutton's Mammoth White, and Veitch's Superb White Cos, while All the Year Round, Veitch's Perfect Gem, and Sutton's Favourite are good cabbage kinds. Other serviceable varieties for general use are: Improved Black-Seeded Brown Cos, very hardy; Hick's Hardy White Cos, an invaluable kind for autumn sowings, being very hardy and of excellent flavour; and the old Hardy Green Hammersmith, which still remains one of the best, if not the very best cabbage kind for winter use. If planted in a fairly dry sheltered position, it will come through the severest winter unharmed. Carter's Harbinger for forcing is a distinct and valuable kind for the purpose, and should be grown by all where winter salads are in great demand.

Aldenham House Gardens. E. BECKETT.

PROFITABLE CUCUMBER CULTURE.

IN answer to Mr. Turner's inquiries which appeared in the GARDENERS MAGAZINE (page 110), I think I can satisfy him with regard to the profitable growing of cucumbers. In giving full particulars of the starting of my plants, and the space occupied, the prices received for each month throughout the season, as I sell all at wholesale prices after supplying the Hall, which is a very large establishment. With regard to discarding cucumbers for tomatos, my opinion is that where there is a good market for cucumbers they well pay as well as tomatos. For instance, where early tomatos are wanted they are more liable to disease than the cucumber, and require much amount of care and attention. The camel-hair brush must be kept regularly at work or your fruit will not set freely, but cucumbers do not require this treatment. The chief point to be considered in relation to tomatos is that if you have a quantity of fruit on hand they can be kept for a week or more when sale is slack without being deteriorated; this cannot be done with cucumbers.

I planted my cucumbers on February 20, in a span-roof house forty-eight feet by twelve feet, with twenty plants of Sutton's Improved Telegraph, I gave them the treatment described in GARDENERS' MAGAZINE of October 30, page 617. Readers will now be able to judge whether my treatment or the treatment given in GARDENERS' MAGAZINE of November 13, page 710, is most profitable. In the first place, I do not consider horse droppings quick enough in its action, besides the extra amount of labour in collecting this off the roads; moreover, if I wanted to use horse-droppings from the roads I should be unable to do so, for they are not obtainable here. There is also an objection to their use as the odour would be most unpleasant in the houses when watering. The extra expense in the labour of collecting and daily mixing the liquid would also be considerable. Soot is beneficial to the plants if used occasionally. I find that five shiliings' worth of Clay's Fertiliser or Peruvian guano will carry this crop through without delay or unpleasant smell. Saving of labour I consider the beginning of profit.

I commenced cutting fruit on the 3rd of April: during the month of April I cut 91 fruit at 6s. per doz.; May, 520 at 4s. per doz.; June, 507 at 3s. 6d. per doz.; July, 507 at 3s. per doz.; August, 195 at 2s. 6d. per doz.; September, 442 at 2s. 6d. doz.; October, 78 at 2s. 6d. per doz.; November, 78 at 2s. 6d. per doz. During the season I supplied the Hall with 200 of the best of the fruit, which makes a total of 2,618. I think if Mr. Turner would try my treatment of cucumbers he would find it far more profitable, with a great saving of labour.

The Gardens, Castle Hall. T. DAVIES.

ORCHARD MANURES.

THE fruit grower having secured a proper selection of fruit trees suited to the climatic conditions of his district, will find it to his advantage to expend a few pounds per acre in manures, for the purpose of adding to the fertility of the soil, or to restore the elements of plant-food extracted from it by the growth of the fruit crops. To use manure when not needed is waste, and, in the same way, to use a manure that contains too much of one substance, but too little of another, is equally waste. Hence the importance of being able to compound manures of the essential elements of plant-food in proportions varying to suit each fruit tree requirements, so that the latter will have all that it wants and no more. The science of horticultural chemistry has during recent years thrown such light on the question of fertilisers, and the study of the requirements of cultivated plants, that we are able now with a reasonable amount of certainty, for every pound spent in suitable manures to expect a fair return for the outlay. All soils consist for the most part of substances which have no direct or immediate use in feeding plants, therefore few soils can do without manure of some sort in order to yield maximum crops. Attention has frequently been called to the very large amounts of reserve nitrogen that occur in cultivated soils. Analysis has shown from 3,500 lb. to 6,000 lb. per acre, taking the loam as one foot deep, indeed, some soils are doubtless so rich from the abundance of their nitrogenous reserve store, that they become too forcing for the purpose of successful fruit growing, inducing an excessive development of wood and leaves, to the detriment of the fruit; or in the case of grape cultivation, the soil may contain too large a proportion of nitrogen in relation to the supply of potash and phosphoric acid, that the fruit would be badly coloured, and would lack its proper sweetness and nutritious character.

In our study of manures for fruit trees, we must start with the maxim that no one manure is suitable for all kinds of trees; and it is only by considering in detail the constituents of plants, the functions of their individual organs, and the conditions for their growth and development, that we can hope to understand fully the application and effect of manures. Plants, including fruit trees, in order to thrive, require certain chemical elements, some of which are supplied by the air and some are derived from the soil. Those supplied from the air are combinations and compounds of carbons, hydrogen, and oxygen. These three elements constitute with the compounds of nitrogen and sulphur, which, in the case of fruit trees, are obtained from the soil, the organic part of the plant. On combustion, either by fire, fermentation, or decay, the organic portion of plants returns entirely, or in part, to the air in the form of gases; while the mineral or inorganic portion of the plant, which is represented by the ashes left behind after complete combustion, consist of potash, soda, lime, iron, magnesia, silica, phosphorus, sulphur, chlorine, and manganese. These non-volatile substances are all derived from the soil, as they are of rock origin. The first five of these inorganic constituents are called bases, and are generally found in Nature with some acid to form sulphates, nitrates, chlorides, phosphates, silicates, carbonates or humates of potash, soda, lime, iron, and magnesia.

Conditions on which the Fertility of Soils Depend.

1. A certain quantity of organic matter is beneficial, for it causes disintegration of the soil, and renders it more friable and better adapted to the development of the finer fibrous tree roots. The nearer the roots are to the surface of the soil the better coloured will the ripened fruit be. It must, however, be remembered that an excess of organic matter causes sourness of the soil, which induces badly developed wood and the formation of few fruit-buds.

2. There must be present in the soil all the mineral constituents required for the special fruit crop under cultivation, and in such form that the food can be readily absorbed by the growing tree. According to the "law of minimum," a soil destitute of any one of these essential ingredients may become more or less unfruitful, since it is the minimum of any one constituent, and not the maximum of others, which is usually the measure of productiveness.

3. A soil may contain an abundance of potash, lime, phosphoric acid, or iron, &c., and yet be very unfertile, because these substances exist as insoluble compounds—as in granite, sand, and the like. Before any mineral ingredient can be absorbed by a living plant, or roots of a tree, it must be dissolved by water, or water made slightly acid. Thus all root-sap is more or less acid.

4. A fertile soil must be of such a texture as to admit free access of air, though at the same time not too porous, but dense and firm enough to retain moisture, and to afford proper support to the growing tree against storms of wind.

How do Trees Feed?

It may next be asked, how do fruit trees feed? Water, of which plants on an average contain 70 per cent., is absorbed from the soil by the tree roots and their root-hairs. This water forms the vehicle of the mineral matters which pass directly into the cellular tissues of the roots, and are thence diffused through the stems, leaves, flowers, and fruit, and constitute after burning the ash of the plant. Nitrogenous food is taken up from the soil by the tree roots in the form of nitrates, which have been produced from ammonia. After absorption this is converted by the plant into albuminoids. Next in order to the roots, the leaves are the most important organs of a tree. These on a full-foliaged tree, possess millions of small mouths which drink in the carbonic acid gas from the atmosphere. From every forty-four parts by weight of carbonic acid absorbed, the tree obtains twelve parts of carbon to build up the organic portion of its structure. It seems incredible (says Professor Anderson) that trees should get almost the whole of their carbon from the four parts of carbonic acid that exist in 10,000 of air; but it can be understood when we calculate that there are 2,160 pounds of air overlying every square foot of land, and in that amount there are about 5¼ ounces of carbon, which is equal to no less than 7 tons per acre.

When we find that in a mangold root crop of 25 tons per acre there is hardly 30 cwts. of carbon, and in a wheat crop of 2¼ tons per acre not more than 22 cwts. of carbon, it can be readily seen that there is constantly floating over every part of the earth a quantity of carbon in the form of carbonic acid gas five times in excess of any crop's ultimate total requirements.

Immediately a fruit tree starts into active growth its roots absorb water and its leaves absorb carbon; five parts of the former with four parts of the latter form starch. This is further acted on by water and converted into glucose or sugar, which substances being dissolved in the sap or juices of the tree permeates its entire structure, giving rise to the various carbohydrates, namely, wood, grape-sugar, cellulose, &c. This process of assimilation and digestion is due in some wonderful way to the influence of the green colouring matter, called chlorophyll, contained in the leaves of trees. In some investigations of Sir John Lawes and Sir Henry Gilbert at Rothamsted it was found that the percentage of sugar was larger in root crops grown by farmyard manure alone than in those with nitrogenous manure in addition. It was higher still when mineral manures were used alone, but here again was reduced by the addition of nitrogenous manures. The fact being that the lower the nitrogenous manurial supply the riper the crop of roots became; and with this ripeness there was found a higher percentage of sugar in roots, a higher percentage of starch in potatos, and a higher percentage of cellulose in the straw of cereal crops; also conversely the larger the nitrogenous manuring the more luxuriant the growth, the less ripe the crop, and the lower the proportion of sugar, starch, or cellulose.

The same rule holds good in the case of wine-producing grapes, which yield a "must" more suitable for wine making when the fruit has been grown on a soil with an excess of potash and phosphoric acid rather than an over-abundance of nitrogen.

Plant Needs.

Here we may inquire as to the differences in the food requirements of different plants. With farm crops we are well informed by the results of hundreds of analyses. Thus we are taught that potatos, beans, and peas need a large amount of potash; wheat, barley, oats, and maize require a good supply of nitrogen and phosphates; while clover, turnips, lucerne, cherries, olives, and vines must have an abundance of lime. Professor Anderson informs us that good potato land will produce excellent peaches, nectarines, apricots, olives, plums, and cherries. Chemical analysis has also shown that the ashes of these plants contain a large amount of potash, which may, therefore, be called the dominant constituent. In like manner, oranges, lemons, almonds, and apples do well on maize and wheat producing soil, and phosphates may be considered their dominant need. The ashes of vines, olives, strawberries, figs, and cherries reveal a large percentage of lime and potash, so that bone dust, ground bones, superphosphate, basic slag, and potash may be expected to benefit these tree and assist in fruit production.

Harpenden. J. J. WILLIS.

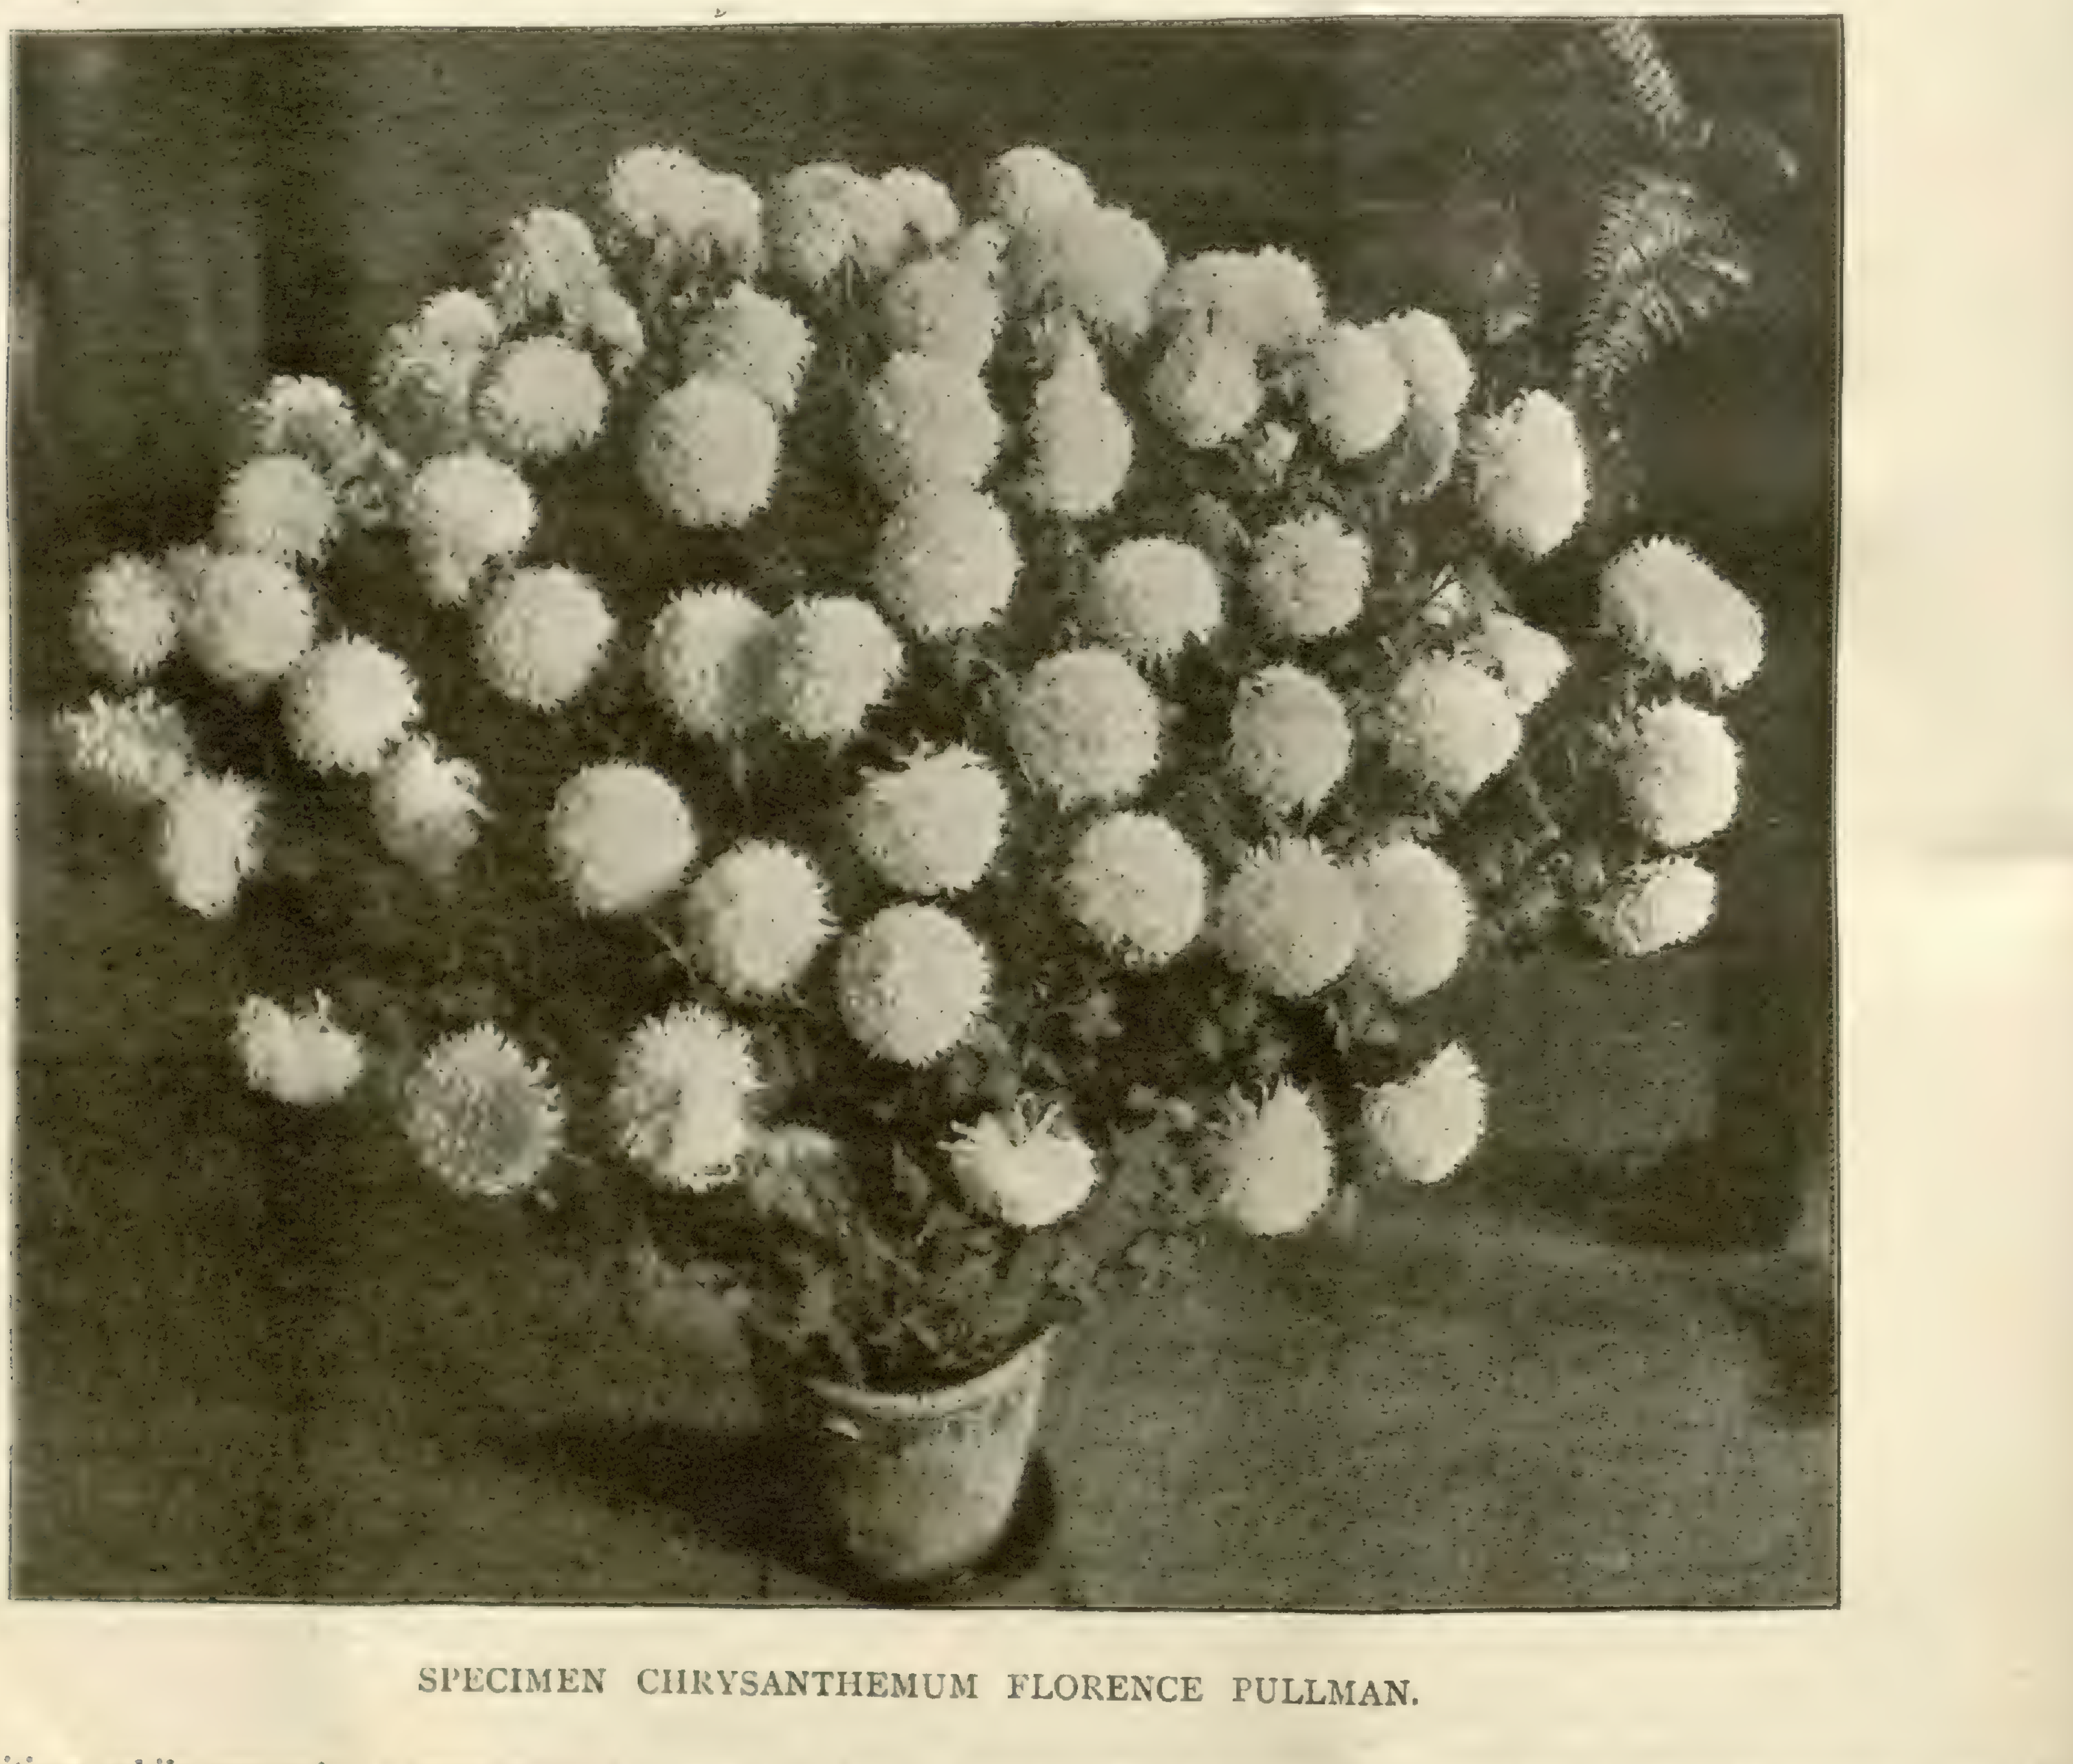
LARGE PRIZES.

YOUR correspondent "Lux" suggests that I might like to say something with respect to the growing increase, seen in so many directions, in prizes for competition at flower shows. Possibly he is, like myself, a non-competitor, and, if so, can afford to regard these matters with an unbiassed mind. I cannot say that I would desire to see exhibitions devoid of prizes altogether; for whilst occasionally, as at the Temple, for instance, it is possible to obtain a grand show without prizes or, indeed, without competititors, of any sort, yet what is so far done in this way for the Royal Horticultural Society would hardly be done for any other society in the kingdom. Again, everyone knows that competitions do furnish an element of such exceeding interest in shows that generally they owe much of their popularity to them. Myriads of good growers and gardeners also will show of their produce only when such stimulus is furnished. But the great increase in the value of prizes at shows, of late so much in evidence, does in my estimation present a serious danger to the permanency of flower-show competitions. We see on every hand now competition amongst show executives to provide the largest prizes, so that prizes are being offered far in excess of the real, or even assumed, value of the respective exhibits. Doubtless the exhibitors rejoice, but, as the frog in the fable said, "What is sport to you is death to me," so may these exaggerated prizes ultimately kill the societies offering them.

It is just as well that both committees and exhibitors should realise that probability, and in time stop what is likely to be so harmful. It is so much better to keep prize amounts to such reasonable sums as means will enable to be offered, and not to attempt doing the big thing and ending in bankruptcy. Then what benefit to horticulture is likely to result from these large prizes? Just take horse racing, in which there is such exceeding competition, although very much of it is fouled by greed and duplicity. During the past few years prizes of literally immense value have grown up in various directions, and the winners have rejoiced over their luck, of course; but can anyone at all familiar with horses affirm that in any way these big sums as prizes have done anything to improve them or breeding? Of course not. It will be the same in horticulture. The societies that offer these big tempting prizes may secure large competitions, but they will render horticulture as a skilled profession or occupation not only of no good, but will inevitably do harm. Nine tenths of the horticultural societies of the kingdom find it difficult enough as it is to hold their own, and if they, too, should be tempted to form a big class or two they will soon come to grief. When we see £20 offered as a first prize for a giant group of plants, which must not only be of first-class quality, but be arranged with the highest artistic skill, there is an impression that the amount offered is far from being excessive; but when this large sum is offered as a first prize for forty-eight or perhaps sixty chrysanthemum blooms, arranged in boxes with little artistic taste, carried with comparative ease, and worth in the market about sixpence each, the offer does seems beyond reason. A. DEAN.

A REMARKABLE SPECIMEN CHRYSANTHEMUM.

WE have on many occasions directed the attention of our readers to the great value of specimen chrysanthemums trained in the form of neat bushes for the embellishment of the conservatory, and as suitable opportunities have offered we have impressed upon societies specially interested in the chrysanthemum the desirability of giving them liberal encouragement. In numerous instances our advice has been acted upon, with the result that they are frequently met with in gardens and at exhibitions with, as we believe, advantage to both. We can fully appreciate the skill evinced in the production of the large and finely flowered convex-trained specimens that are occasionally represented at competitive gatherings, and are ever ready to bestow upon the exhibitors the praise they so well deserve; but we are fully alive to the fact that the production of these specimens imposes a severe tax upon both the time and the skill of the cultivator, also; that, however meritorious they may be, they do not so readily lend themselves to artistic treatment in the arrangement of the conservatory as do specimens that have been allowed a greater latitude in making their growth, and that they are consequently less useful where chrysanthemums are grown exclusively for home decoration. Bush-trained specimens, which usually form a magnificent feature at the Hull exhibitions, while presenting a more natural appearance than the convex specimens, are free from the defects characteristic of the plants grown with a single stem in accordance with the practice that obtains in the production of exhibition blooms, and can be readily arranged to produce effects at once rich and pleasing. Hence the desirability of both extending and improving their cultivation. With a view to assist in bringing about these desirable results we have figured some of the finest examples that have come under our notice at the English exhibitions, and we now present our readers with an illustration of a splendidly developed specimen of Florence Pullman, which formed a conspicuous feature of the exhibition of the Pennsylvania Horticultural Society's exhibition held at Philadelphia in November last. This specimen is specially remarkable for the fact that instead of having been grown in a substantial compost such as is usually advised for chrysanthemums cultivated in pots, was from a cutting grown exclusively in Jadoo fibre, and a stronger proof of the value of this material as a medium for the roots of plants that require a liberal supply of food in their development could not well be desired. We understand that the pot in which the specimen was grown was nine inches in diameter; and assuming this to have been the case it is not difficult to form a correct estimate of the dimensions of the plant, and of the size of the individual blooms, or of the adaptability of Jadoo fibre to the requirements of chrysanthemums.



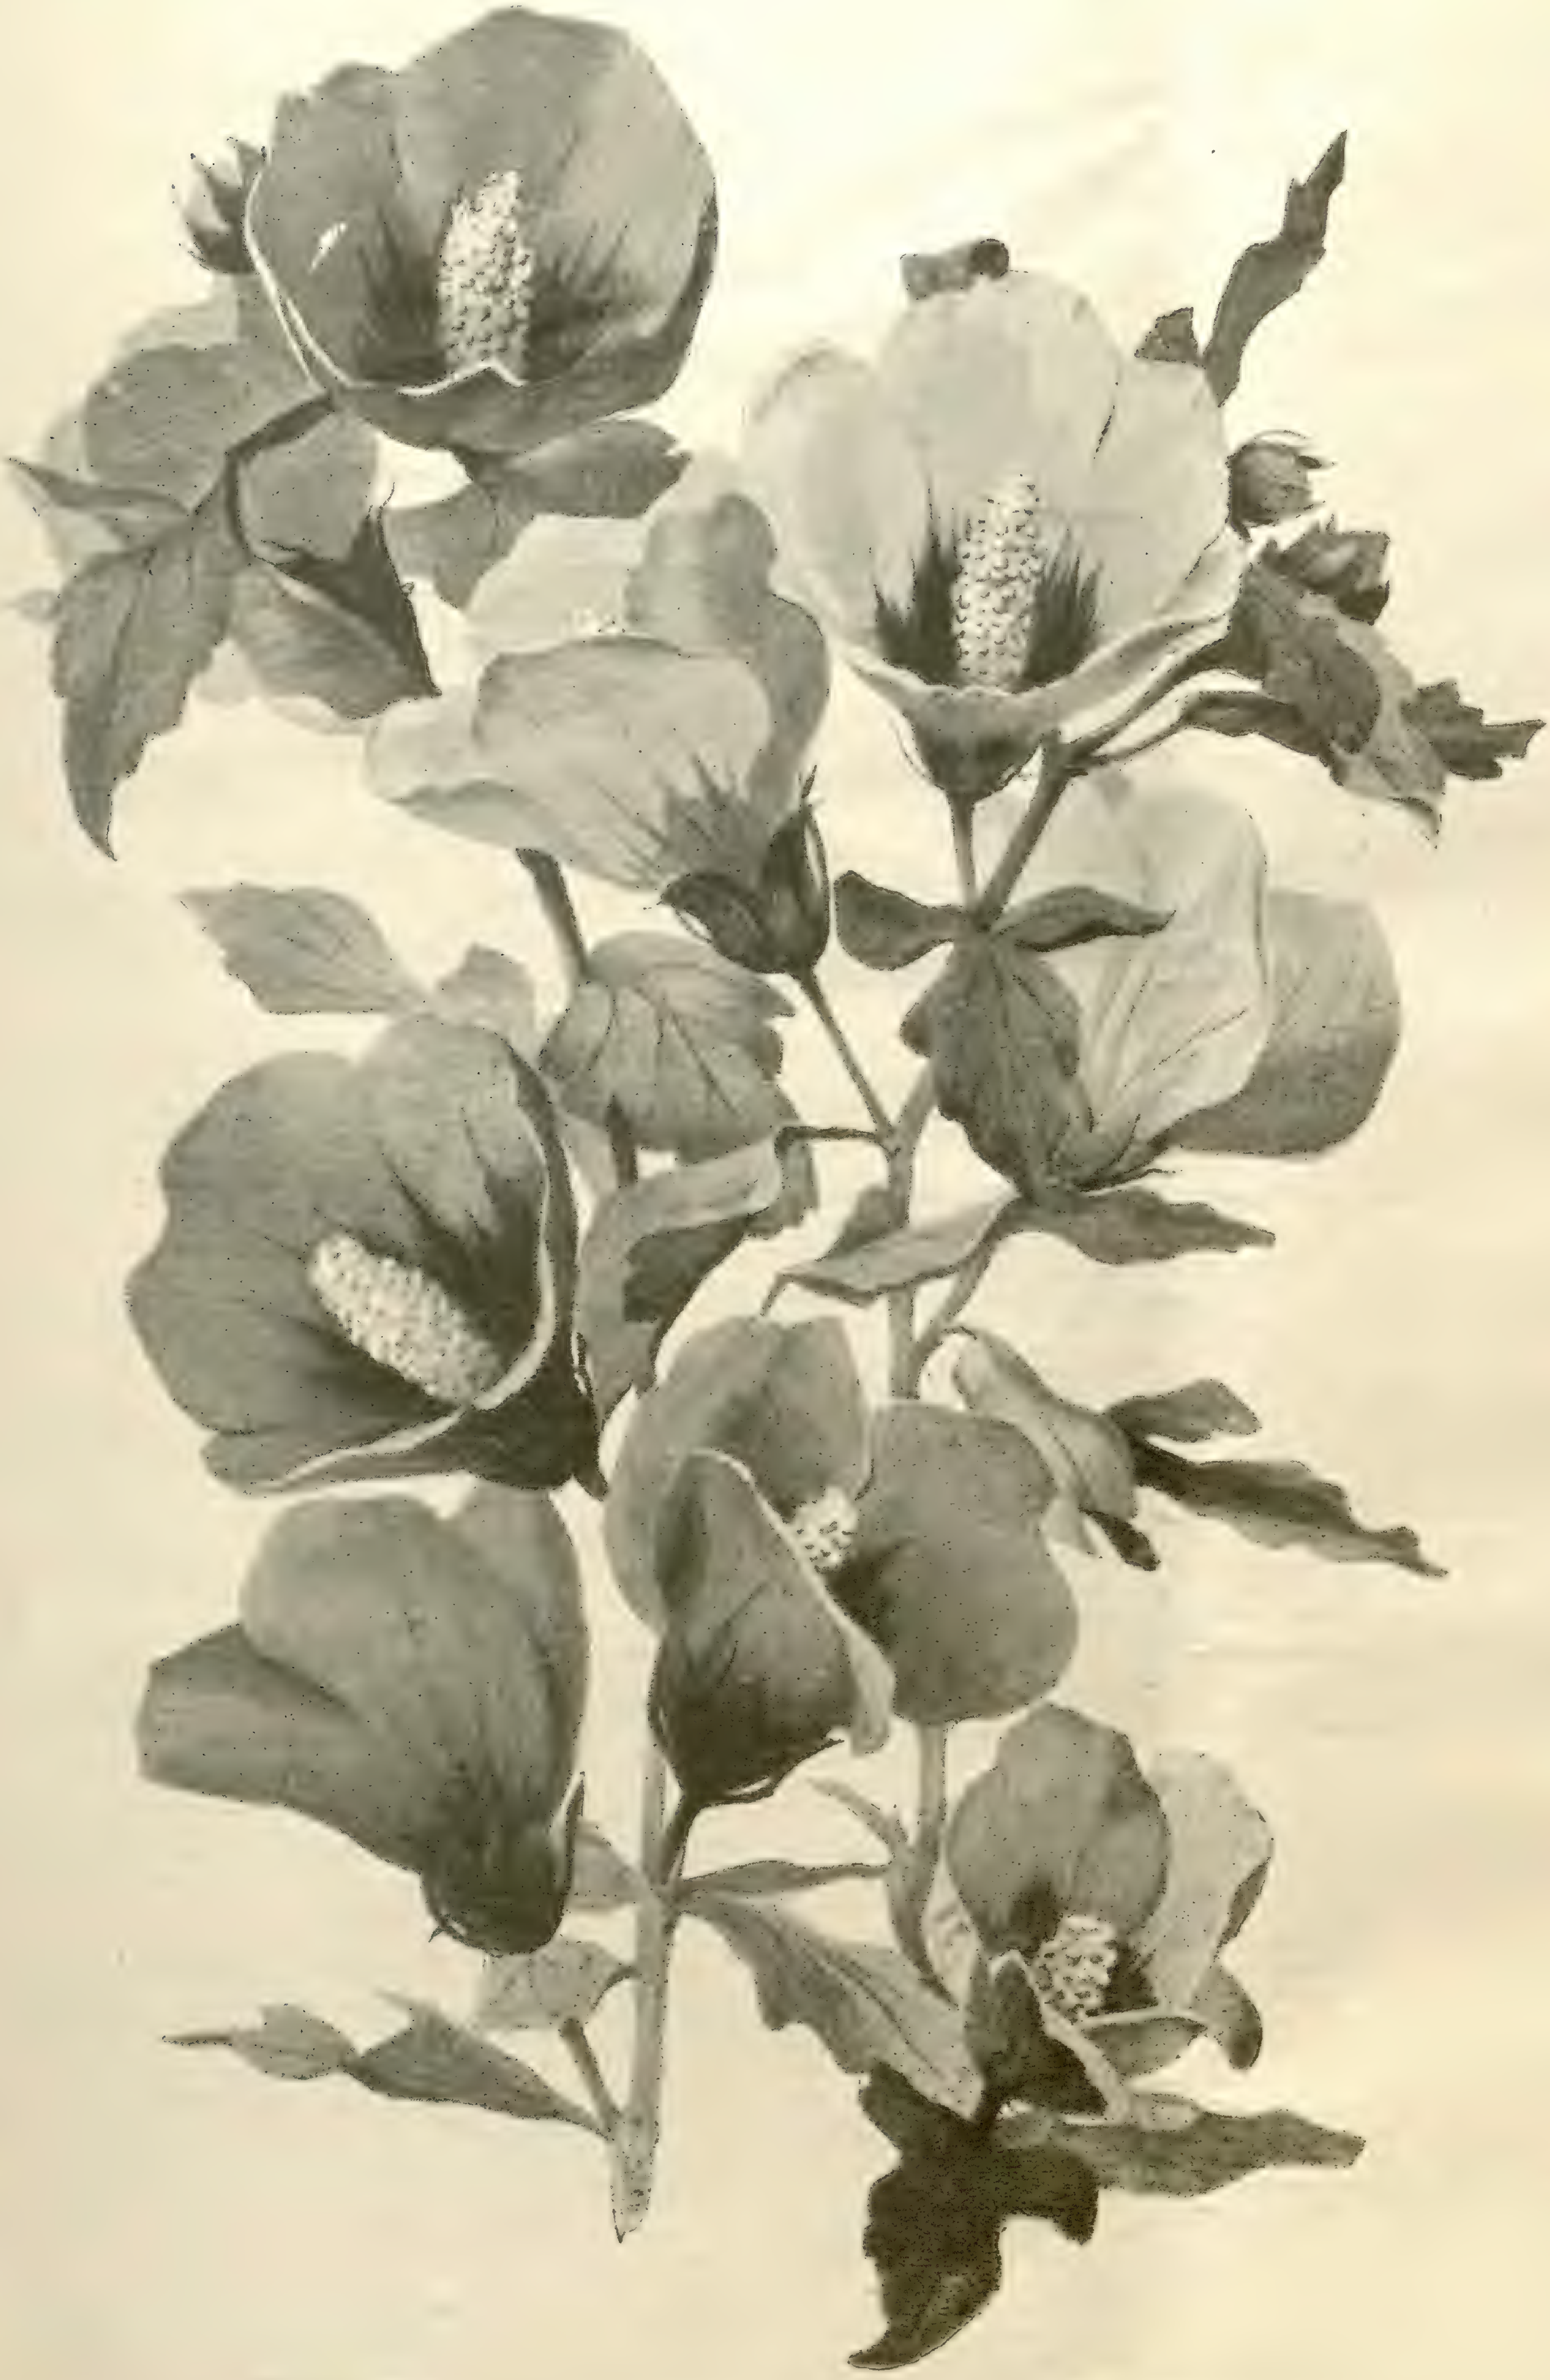
SPECIMEN CHRYSANTHEMUM FLORENCE PULLMAN.

HIBISCUS SYRIACUS.

THE Syrian hibiscus, known also as Althæa frutex, is the only species in a fairly large genus that is both ligneus and hardy in this country. In the neighbourhood of London and southward it is perfectly hardy, while in the Midlands and northward it will require some protection during winter, or has to be cultivated against a wall to be a success. All the numerous seedling varieties that have been perpetuated need similar treatment, and all delight in a light, porous, and rich soil and a warm position. In the drier soils of Surrey and Sussex the Syrian hibiscus grows freely and flowers during August and September with wonderful profusion, its succession of flowers fully making amends for the evanescence of the individuals. The leaves are comparatively small and variously lobed, wedge-shaped and toothed. The flowers are large and vary in colour from rose to deep red and purple; both single and double forms are in cultivation. In height both species and varieties are from six to eight feet when fully grown, and the habit is fastigiate rather than spreading. They are deciduous, and the erect branches are freely produced.

Hibiscus syriacus was introduced from Syria about 1596, and was certainly in cultivation in England previous to 1629, for Parkinson alludes to it at the latter date as being somewhat tender. As late as Miller's time there were no double-flowered varieties, but as the species became popular, and its seedlings exhibited great varietal tendency, double forms were soon selected, and these became very popular on the Continent; they are now quite common, but not so popular in this country as the single varieties. Such immense quantities of early spring flowering trees and shrubs have been planted of late years that there has been a tendency to ignore or forget those that are beautiful in late summer and early autumn, consequently a vast number of new gardens do not possess Hibiscus syriacus in any of its charming forms. The reaction has, however, set in, and among autumn-flowering shrubs the Syrian hibiscus will be greatly in demand. As already instanced, there are varieties to please all tastes, and two of the most handsome and effective are depicted in the present issue, the light one being H. s. Painted Lady, rose tinted with rich red blotches, and the other H. s. cœlestis, blue with purple bases to the segments. The sprays represented came from plants grown at the Coombe Wood Nurseries of Messrs. J. Veitch and Sons.

A few other of the most attractive forms of the Syrian hibiscus are H. s. Totus albus, white; H. s. rubrus plenus and H. s. roseus plenus, respectively red and rose coloured double varieties; H. s. amaranthus, purple; H. s. violaceus atropurpureus, dark violet; H. s. Violet Claire, a bluish, double form of great beauty; H. s. cæruleus plenus, double blue; H. s. albo plenus, double white; H. s. anemonæflorus, H. s. Leopoldi, H. s. Pompon Rouge, H. s. Ardens, and H. s. Duc de Brabant.



Painted Lady. Cœlestis.

HIBISCUS SYRIACUS VARS.

WORK FOR THE WEEK.

THE KITCHEN GARDEN.

IN a weekly calendar of kitchen garden work it should be remembered that the writer gives his experience as far as possible of the place where he resides, but as seasons and soils somewhat vary, and as he has to write his notes a week or so beforehand, it is not always possible to state exactly the way to proceed ; it may, however, be taken that such work may be done as near as possible to the dates given. One of the most important duties of the kitchen gardener at the present time is to see that all tender vegetables are well protected from frost. In many places potatos that are in clamps become frosted for want of litter being placed over the heaps in severe weather, therefore this should receive attention at once. Carrots that were sown in the autumn with a view of supplying fresh tender roots during winter and early spring, will be of little use if the soil is allowed to get frozen in such a manner that they cannot be drawn when required. A small quantity of dry bracken or leaves will ward off an ordinary frost, particularly in dry, sandy soils, but should there be any signs of severe weather, material should be made ready to afford further protection. Lettuce and endive must receive attention in like manner. Most gardeners who have to contend with heavy soils know the difficulty there is in keeping celery through the winter. If boards about a foot wide are nailed together at right angles, and these are placed on the tops of the ridges they will prevent the rain from running down into the hearts of the plants. The ridges should be covered with bracken or litter to ward off the frost, and if this be done in time the celery will remain quite good till the spring. In some establishments there is a great demand for forced rhubarb, seakale, asparagus, mint, tarragon, chicory, endive, and the like. Now all these require some special preparations. Mint and tarragon rooted in boxes in August last may be placed in heat as required, but where this was not done roots must be taken up from the open ground and placed in pots or boxes filled with light, rich soil, taking care not to bury them too deeply. Chicory, endive, rhubarb, and seakale are best forced in a dark cellar. It is impossible to take up the roots of these when the ground is frozen hard, therefore a sufficient stock should be lifted and covered that they may be introduced into a gentle warmth as required. It is essential that if subjects of this description are to be had in the finest possible condition that they are grown in absolute darkness, and no more fire heat applied than will promote a healthy growth ; indeed, if they can be produced without fire heat at all so much the better. No more should be introduced into the forcing house at one time than is necessary for the requirements of the establishment. The roots of asparagus lose much of their vitality if lifted for any length of time before being forced, and for this reason the beds intended for forcing should be covered with litter so as to exclude the frost, the stools can then be taken up as required. This vegetable is always the most tender when forced on a gentle hot-bed made of fermenting material, therefore a goodly quantity of this should always be kept in readiness.

A very important item at this time of the year is that of making up the seed order, and, as many seeds are wanted very early, no delay should now be made, or anything allowed to take place, that prevents the order being made out at once and sent in. When received, the seeds should be kept dry and in an even temperature till such time as they are required for sowing. It is only by close attention to the requirements of a place that a true guide can be had of the necessary quantities of each kind. When the ground is frozen hard, the wheeling on of manure should be proceeded with, as such work can always be done with more dispatch when the ground is dry. It is, however, best not to delay the work of manuring till late in the season, if this can be avoided, particularly if the material is only half decayed, as it has not time to rot before the crops are planted, which, in the case of many plants, is most injurious. Ground intended to be sown with parsnips, carrots, beet, salsafy, and scorzonera should on no account be manured so late in the season, unless the manure is placed at least two spits deep, or the roots will become forked and ill-shaped. That intended for cauliflower, peas, and such other vegetables as require rich ground, should be liberally manured and deeply dug as soon as possible, particularly if it be of a light sandy nature, that the soil may have time to settle down again before the crop is sown or planted. Care should be taken to have each plot of ground marked out where it is intended that each vegetable shall be grown, that there may be no mistake at the time of sowing. Ground intended for onions cannot well be too rich, neither can the soil have been moved too deeply, provided it is of good quality, and, as such work cannot be done later on, when other things become more pressing, this, if not already completed, should be taken in hand the first favourable opportunity.

The clipping of hedges, where there are any, surrounding the garden can also be proceeded with when the ground is hard, while, if we should have a fall of snow so as to put a stop to outside work, such work as making seakale sets, labels, and placing potato sets on their ends in shallow boxes could be done. The former, if made now and covered with decayed leaves or short litter, so as to keep them moist and protect them from frost, will frequently have callused and commenced to root by the time they can be planted, and will therefore be much more forward than those made and planted later on. The advantages of having potato sets started are manifold, but the growth made should always be stout and robust, and this can only be made in a comparatively low temperature, where light is freely admitted, and for this reason, those intended to be planted early should receive attention at once.—H. C. PRINSEP, *Buxted Park Gardens.*

FRUITS UNDER GLASS.

THE first or second week of the new year is an excellent time for those who have only two or three vineries to commence forcing for the earliest crop. Earlier than this the crop is more or less out of season, and can with difficulty only be had of high quality ; but after the days begin to lengthen forcing is an easy matter, and with ordinary care the vines make good wood for the succeeding year and do not in any way suffer. Supposing that the vines have been subjected to the usual cleaning and are now suspended, so that the ends of the rods are lower than the other portions of the vine (which will make them break more regularly throughout), the house should be closed and kept for the time being with a minimum temperature of 50 degrees. The border should be well watered with tepid water, so that it is thoroughly moistened throughout. A gentle hot-bed of leaves and manure built inside the house will help to keep up the necessary temperature, and the slight escape of ammonia from the bed will in other ways help the vines. A slight syringing of the rods once a day before noon will be all that is requisite in a house with such a hot-bed, and care must be taken not to over-do the supply of atmospheric moisture. Some people do without the syringing altogether, and there is much to be said for the method, but personally I like to moisten the rods once a day until the buds are ready to burst into leaf. The outside border will require covering in cold districts, but I do not favour the hot-bed system for these, and only cover with sufficient leaves, litter, or bracken to keep the soil from being frozen, for unless this takes place the roots will work quite freely enough to keep the vines growing healthily without subjecting them to artificial heat, therefore a few inches only of covering material is necessary. Where vines are planted in outside borders, and led inside through holes in the front wall, the outside portions of stem should be thoroughly well protected with hay-bands or some other covering, and any portion of the holes not filled with the stems should be closed up also, to prevent cold currents of air. I have known a complete collapse of growing vines to take place from neglect of this protection during a sudden spell of sharp frost, and any freezing of the sap will give such a check as to cause flagging, if nothing worse.

Pot vines, being of no further use after fruiting, may be driven along briskly if required very early, always remembering, however, that the slower in reason their progress is the better will be the colour of the fruits. Keep the plunging material at a uniformly brisk heat, and afford ventilation as freely as may be, during the forenoon, without creating draughts ; be careful, though, that no front air is given ; all that is needed should be given at the apex of the roof or lights. All late vines from which the bunches have been cut should be pruned as soon as possible. Opinions vary as to the best method of pruning, and it is only needful to say here that close pruning results generally in the most compact and useful bunches while pruning to the "best, *i.e.*, the plumpest bud near the base of last year's lateral, will give bigger and looser bunches. Those who prefer the former may cut back quite to the last bud on each shoot without fear of lessening the chances of a good crop. Figs may now be started, and where the trees are planted out and grown with their heads close to the glass there is no reason for further delay, as the trees will have their first crop ripened in time to produce an excellent and continuous second crop, that will last well into the autumn. The first trees, say of Brown Turkey, started now, will begin to ripen their first fruits early in April, and continue almost throughout May, after which there will be a break, averaging from a month to six weeks, before the second crop ripens. To cover this break it will be well to start another house in six weeks or so from now. Pot trees with the fruits well advanced may now be given a higher temperature, say 60 to 65 degrees at night, and have liberal doses of liquid manure as required. Trees started now do well with a temperature as advised for starting the vines. Any trees which have not yet been cleaned should be treated at once, always remembering that the young wood of fig trees is very susceptible to injury from the use of strong insecticides, and I never allow anything of the sort to be used on the wood made during the past season.—J. C. TALLACK, *Livermere Park Gardens.*

THE PINK COLOUR IN CHRYSANTHEMUMS.

THE economic importance of chrysanthemum-growing (which in this state is estimated to involve more capital than peach cultivation) justifies the attention paid to this subject by the Cornell Experiment Station. Chrysanthemums are not yet quoted in market reports by names of varieties as roses sometimes are, but the prices are usually given for the three prominent colours—white, yellow, and pink. The various shades of pink seem to be exceedingly unstable. One of the popular commercial varieties is Fred Walz, which I have frequently seen in three or more easily distinguishable shades, although the plants seemed to be grown under very similar conditions. This variety being somewhat stiff and formal in outline, is easily ruined for artistic effect by unevenness of colour. The mere fact that the pure pink of Mr. F. Schuyler Mathews's colour-chart has not yet been attained in chrysanthemums is not so serious in itself, because that is only one particular shade. There seems to be an entire series of colours whose value is determined far more by the skill of the cultivator than by the variety. Amaranth, crimson, rosy pink, crimson pink, light pink and blush-white are some of the names of trade catalogues which represent a gradation from the deepest shade of the series down to pure white, and it seems probable that any of these shades may in some cases be obtained from a single variety. Not all varieties, of course, are so highly susceptible as this, but frequently the difference is enough to make the flowers unsaleable. The control of colour, therefore, becomes a problem of great interest.

The problem is doubtless a complicated one. There seem to be at least five factors concerned, any one of which may change a pink to a white. The choice of buds is said to be sufficient in some cases. J. H. Woodford, one of Mr. Spaulding's novelties, is advertised as shell-pink from terminal, and pure white from crown-buds. Over-propagation is generally thought to weaken colour. Temperature and ventilation (the two factors can hardly be separated in greenhouse practice) are advertised to produce three distinct and desirable shades in Mrs. Colonel Goodman. Mere position (in pots, beds or benches) should not in itself make a difference, but in practice it does. The effect of shade is variously stated. And most complicated of all, the food factor is known to influence colour, but just how is a mystery.

Thirty-one varieties advertised as having various shades of pink were grown here under the same conditions. Fourteen gave white flowers with only a trace of pink at most in a few cases. Three others had much less colour than their descriptions imply. I cannot explain such a condition. The general health of the plants was excellent. The four flowers on each plant averaged about six inches in diameter.

Last year I noticed in another place some white varieties which showed pink. Among them were such important sorts as Our Mutual Friend and Marie Valleau, the latter, however, being less frequently described as pure white. The food being much richer than our own, especially in nitrogenous matter, I suspected that an extra supply of nitrogen might have called out the pink colour which we had never observed in these white varieties. Mr. E. G. Hill warns his customers not to use nitrate of soda in the cultivation of certain light pink varieties, as it produces a deeper and unpleasant shade.

It was convenient to single out only two of the supposed factors this year, and the experiment has turned out contrary to my expectation. The extra amount of nitrogen did not deepen the colour, but the flowers proved very sensitive to shade. Shade is said by some to deepen the colour, but the reverse was true in this case. The difference was perceptible at a glance in the case of Mrs. Perrin, Madame Felix Perrin, Marie Valleau, Helen Bloodgood and Iora, and in a lesser degree with William Simpson and Maud Dean. This difference would not prevent the sale of Iora, which is usually uniform in colour, whatever the shade may be. The varieties Mrs. Perrin and Madame Felix Perrin, however, lost their characteristic, sparkling, rosy colour, and were not of a saleable character. Some of these varieties were shaded from the time the buds were the size of marbles until they came into full flower. Others had already burst their buds and were out an inch or more before the glass overhead was whitewashed. I know nothing about shading chrysanthemums during the purely vegetative phase of their life. It seems clear, however, that during the reproductive phase the forming flowers are weakened in colour by shading. There was only one contradictory plant among twenty-five. It is a common complaint among florists that the pink colour stays only a few days after the flower opens, and perhaps sunlight and shade cannot then arrest the fading. The results with the nitrogen factor were not conclusive. At any rate, we did not force pink into white varieties as Lenawee and Mutual Friend.

Ithaca, N.Y. WILLIAM MILLER, *in Garden and Forest.*

VARIETAL DEVELOPMENT IN BRITISH FERNS.

(Concluded from page 13.)

IN 1868 was found by R. Mould, of Ilfracombe, a small plant (Athyrium filix-fœmina Clarissima) which was destined afterwards to become one of the most famous of varieties. Mr. Moule does not appear to have thought very highly of his find, and to Captain, afterwards Colonel, Jones belongs the credit of perceiving and afterwards developing its capabilities as an ornamental variety; while to Mr. Druery belongs the honour of first propagating it, and of thereby bringing to light a botanical phenomenon absolutely new to science and of great importance from the evolutionary point of view. A phenomenon, too, which is now seen to be widely spread among ferns, and abundantly evident to those carefully looking for it. I strongly recommend you all to look for it, especially among those varieties which are supposed to be barren or imperfectly fertile. In the same year (1868) was found Adiantum capillus-veneris cornubiense, a beautiful form, which is not so well known as it deserves to be. Also Polypodium vulgare grandiceps Mrs. Fox, Mrs. Wilson's Athyrium filix-fœmina rectangulare, and many other notable things.

The year 1869 produced some fine things, one of the most notable being A. f.-f. plumosum Wills, perhaps the grandest of the wild-found plumosums. It is said to have been found not so much by Mr, Wills as by his pony, which insisted on making a detour round a piece of waste land and then suddenly stopped dead. On the doctor casting his eyes to the ground he found he was on a feathery bed (not a feather bed). Alighting he severed with his crooked stick a large clump, as much as he could lift to the saddle. Other good things of this year were Polystichum angulare perserratum Wollaston, P. a. divisilobum proliferum Bagg (better known as Henleyæ), P. a. grandiceps Moly., and Athyrium filix-fœmina multifidum tenue Wilson (a very neat thing).

In 1870 Mr. Howlett, of Oxford, raised A. f.-f. Kalothrix, the most refined of all Lady ferns, and, under proper conditions, one of the most delicately beautiful of ferns. The origin of Kalothrix is involved in some mystery; all that is known being that it was raised from a plumosum which was growing in the Oxford Botanical Gardens. This was supposed to have been traced to a Horsfall plumosum in the Chelsea Gardens. It is recorded, however, that there is in the Sherardian Herbarium, Oxford Botanical Gardens, a frond of Kalothrix, or something very like it, which was gathered in the Mourne mountains many years before Howlett raised his plants. This seems to suggest very strongly that the plumose parent of Kalothrix came from spores of this Mourne mountain plant, seeing that Kalothrix itself produces a percentage of plumose offspring. I intend to try to clear up this point, if possible, the first time I visit Oxford. In the same year was found Mrs. Hodgson's Athyrium filix-fœmina subplumosum, of which I have never seen more than a single dried frond, but which struck me as being in the way of Kalothrix and almost equally beautiful. It would be interesting to know whether this plant is still in existence. Among many other good things of 1870 may be mentioned Lastrea propinqua cristata Barnes, Polystichum angulare divisilobum cristatum, Ivery, and Lastrea dilitata cristata, gracilis Roberts. This last is very pretty in the young state, but as it attains maturity it is marred by a certain depauperation which destroys its symmetry. If this defect could be eradicated from its constitution, this plant would be a really good thing; but as it is, few people care to grow it. If there were anything in the idea of spores from a particular part of a fern being different in constitution from those of another part, and tending to reproduce the character of the part from which they arise, it ought to be no difficult matter to get rid of the depauperation; but, though many thousands of seedlings have been raised, the spores of which would presumably be selected from good fronds or parts of fronds, I have never heard of one being raised which was free from the radical defects of the parent. This difficulty in getting rid of defects is a strong testimony to the truth of Weissmann's theory, that the germ plasm is the same in all parts of the plant.

Another very striking find of 1870 was Mr. Stabler's Asplenium trichomanes confluens. This is another of the ferns which have been, by many eminent authorities, regarded as hybrids; and it is also another case in which this opinion appears to me to have been arrived at upon insufficient evidence. The chief points in favour of the "hybrid" theory are the large size of the fern (approximating remotely to that of A. marinum), and its sterility; perhaps the thick and rigid character of the stipes may be counted as another, but really this is part of the first point—that of size. On the other hand, there is nothing of the outline and but little of the texture of marinum in confluens. Further, Mr. Barnes examined very closely the wall in Levens Park where confluens was found, but not a trace could he discover of either A. marinum or A. adiantum-nigrum, the only other species at all likely to have contributed to the supposed hybridisation. Moreover, other confluent forms of trichomanes have been found by at least four other people. Two of these (found by Mr. Forster and Mr. Smithies) I have seen, and they seem to be equally barren with Mr. Stabler's form, and moreover, though small when found, they are capable, when grown under the same conditions, of approaching if not of equalling Mr. Stabler's fern in size. I have seen however A. trichomanes incisum, under the cultivation of Mr. Robinson, York, grow to a larger size size (sixteen inches long by an inch wide) than I ever saw or heard of confluens attaining to. There is then, it seems to me, quite as much evidence of the hybrid origin of incisum as of that of confluens. No one suggests, however, that incisum is a hybrid fern.

In 1871 Mr. Barnes found the crested Lastrea montana, from which he afterwards raised his coronans, ramo-coronans, and grandiceps. This was the first really crested montana, the much older so-called L. montana cristata found by Huddert being a polydactyla rather than a cristata. We have here an instance of the odd results which followed from the haphazard system, or rather want of system, upon which fern varieties were first named. The name cristata was given to a polydactylous form—then, when a really crested form was found, it was thought it could not be named cristata because that name was already in use; and so the fanciful name of coronans was given to it—a name which does not really express its character. It would have been all the same had the original cristata been really crested (which sometimes indeed it is, though less perfectly than the other). It had not then occurred to the sponsors to give ferns of similar character the same name, distinguishing them from each other by the name of the finder. What Mr. Barnes did in L. montana Mr. Glover did the same year in Pteris aquilina, being assisted in the raising by Mr. Mapplebeck, Mr. Forster, and others. In the same year was found John Wilson's exceedingly fine crested Lastrea paleacea, a most distinct and handsome form quite different in habit from the old cristata

In 1872 was found Athyrium filix-fœmina plumosum divaricatum, a form which was not thought very much of at the time. It was not until some years afterwards, when Mr. Tyldsley had grown it to its full size and developed its character, that it was recognised as belonging to the first rank of wild-found plumosums. Another good plant of the year was Isaac Hindson's Pteris aquilina congesta, as were also Blechnum spicant trinervium coronans Barnes; Polypodium angulare tripinnatum Padley; and Lastrea paleacea polydactyla Dadds. In 1873 was found Mr. Moly's Polystichum latifolium, a grand form, which is far too little known and far too little grown. Also P. aculeatum acutilobum Wills, and P. angulare perserratum Patey. In 1874 Mr. Barnes did for Lastrea dilitata what he had previously done for montana, finding a wild fern which was the parent of a series of grand crested varieties. Another prize was Moly's Polystichum angulare divisilobum robustum, a grand and noble form, to which justice can only be done in the S.W. A crested form of parsley fern was also found. In 1875 came Hadwin's plumose polypody, perhaps the best of the Cambricum section, and Polystichum angulare divisilobum laxum Wills.

The sensation of 1876 was P. aculeatum pulcherrimum or rather plumosum, as I believe Mr. Wollaston on second thoughts, and as I believe more correctly, named it. It was found by one John Bevis, a labouring man, who had, as I understand, little if any knowledge of ferns, but whose name will, in consequence of this happy accident, be handed down as the discoverer of one of the grandest ferns ever found. This is a fern absolutely free from faults of any kind, lovely, graceful, and distinct, it is absolutely constant, perfectly symmetrical, and a good grower. In its literal sense the name pulcherrimum is not only appropriate but likely to remain so, for it is doubtful whether a more beautiful aculeatum will ever be found or raised. Its analogies are, however, I think, rather with plumosum than with pulcherrimum in angulare. Other good things of the year were Lastrea montana plumosa John Titterington—a very fine form, though afterwards surpassed by Mr. Whitwell's find in 188—; Polypodium vulgare cristatum of Clewarth, better known as Forster's cristatum, because Mr. Forster first rescued it from oblivion, and afterwards refound it in its original habitat; and Blechnum spicant ramo-cristatum, of Maunder—a form not so remarkable in itself as in its offspring, since it produces from spores some forty per cent. of densely conglomerate offspring, thereby differing from other similar ramo-cristate forms.

The year 1877 is famous for the discovery of two very fine Polystichum angulare varieties by Mr. Phillips, viz., his rotundatum and his setosa-cuneatum, two of the best of the many good things Mr. Phillips has found. Another very remarkable find of this year was Mr. Whitwell's Blechnum spicant paradoxum—a form which, so far as I know, is absolutely unique among ferns, having a third row of pinnæ rising perpendicularly from the mid-rib of each frond. When I last saw this plant it was in a bad way, both morally and physically, but I trust that this year Mr. Whitwell can give a better account of its health and character.

The year 1878 produced Athyrium filix-fœmina setigerum Garnett, a lady fern which, though pretty and distinct in itself, is yet more remarkable on account of the offspring it produces. These, as you all know, tend to be percristate, and from them even densely crested forms can be raised. I imagine the possibilities of setigerum are even yet far from being exhausted. The botanical sensation of the year was Mr. Lowe's "hybrid" cruciate aculeatum, produced by crossing Polystichum angulare cruciatum with P. aculeatum densum; this was one of the earliest, if not the first, cross produced intentionally between two distinct species of ferns. Since that time, but especially within the last two or three years, Mr. Lowe has been successful in the raising of still more remarkable fern hybrids—having crossed not only distinct species but ferns belonging to different genera. Of these things, however, Mr. Druery can tell you more than I can. The same year (1878) saw the origin of the wonderfully beautiful plumose divisilobes in P. angulare, which were the result of the collaboration of Colonel Jones and Mr. E. F. Fox. I should like to say more about these ferns, but time is short, and I have endeavoured to make this paper a record chiefly of ferns found wild rather than of those raised under cultivation.

Passing on to the year 1881, we find Mr. Druery's Blechnum spicant concinnum cropping up; this was at the time, and I believe is still, the most beautiful thing of its kind. Another good thing of the year was Westlake's Lastrea montana angustata. In 1882 Mr. Lowe found his Asplenum trichomanes Trogyense, a very beautiful fertile incisum, which will, I trust, in the future be the parent of many good things. In 1884 Mr. Forster picked up his Blechnum crenato-congestum, which when found was one of the prettiest and neatest blechnums I have ever seen. Unfortunately, it afterwards lost the beautiful crenate, or rather dentate, character which distinguished it from all other congested forms; and, though still a good imbricate variety, it has fallen from its unique position among dwarf blechnums. In 1886 Mr. Smithies found his Las. montana grandiceps, the only true montana grandiceps which has, so far as I know, been found wild. The year 1888 produced Mr. Whitwell's Lastrea montana plumosa, which remains, I believe, so far the finest plumose form of the species.

The ferns of the subsequent years I must leave to be dealt with by Mr. Druery. I have scarcely attempted to deal with the many beautiful and interesting things which have been raised from spores by Mr. Lowe, Mr. Druery, Mr. Clapham, and others, and I have been perforce compelled to omit even the very mention of a great number of first-rate things which have been found wild. The chief thing that strikes me in looking over the history of varieties is, that while we may obtain modifications and developments and combinations of characters from raising seedlings under cultivation—the really epoch-making varieties—the plumosums, the pulcherrimums in angulare and aculeatum, the A. f.-f. Clarissimas, the best polypodies both crested and plumose, the choicest blechnums and aspleniums, have, with very few exceptions, come direct from the great womb of Nature as wild finds.

A Home for Horticulture.—A good deal of reference is just now being made to the proposal which enjoys so far-fetched an appellation. The term is a very ambitious one, and it seems to imply that poor horticulture is a sort of peripatetic Jew that has long been wandering in the desert for years, and now seeks wings and needs a final resting-place. Happily no such condition exists. Horticulture lives and moves all the world over, and especially does it so all over Great Britain. After all nothing more is meant by that much-too-pretentious appellation than a mere show or exhibition hall for London, which is certainly a big centre, although it may not be quite the "hub" of the universe. No one can find fault because the subject is from time to time mooted. It has been so before, when so powerful an aid as Baron Schröder did his best to create this "home" but failed. Let the matter be mooted every year if desired, but who can hope to succeed in raising the needful £50,000 to £60,000 where the Baron failed? There is the want undoubtedly, but to be of any real service the satisfying element must be very large and very costly. Only a building twice the area of the James Street Drill Hall, having also round it a very broad gallery easily accessible by flights of stairs, and well-lighted and warmed, would at all meet the requirements of the various societies it is proposed to accommodate; and if, in addition, the basement contained dry cellars, the ground floor were offices and shops, and the hall with lifts were above, does anyone think—seeing how terribly costly land is in London—that such a building could be erected under £100,000?—A. D.

EXHIBITIONS AND MEETINGS.

WORCESTER AUXILIARY GARDENER'S ROYAL BENEVOLENT INSTITUTION.

THE annual meeting was held at the Guildhall, Worcester, under the presidency of Mr. W. Crump; twenty other members were present. Mr. J. H. White (hon. secretary and treasurer) submitted the statement of accounts, from which it appeared that the receipts for the past year had been £71 9s. 6d. (including the twenty guineas received as admission to Madresfield Court Gardens on the occasion of their being open to the public early last summer. The expenses were £7 0s. 10d., the sum of £63 having been forwarded to the parent society in London. During the past season there had been a lack of spontaneous donations which would account for the small balance in hand. Thanks were accorded to Earl Beauchamp for so kindly aiding the cause by throwing open his beautiful grounds for the society's benefit. The committee were glad to report that Mr. Davies, the county candidate, whose nomination they supported at the last election of pensioners, was successful; two candidates from the county had been nominated this year, the particulars of which would soon reach the subscribers. Earl Beauchamp was re-elected president, and Messrs. W. Crump and J. H. White, life-governors. In acknowledging the vote of thanks for presiding, Mr. Crump observed that during the last two years the society had forwarded £227 15s. to the parent society. He also referred to the death of Lord Hindlip, a strong supporter of the cause; and a vote of condolence was passed and ordered to be forwarded to the family.

SHIRLEY GARDENERS' ASSOCIATION.

At the recent monthly meeting of this energetic association, Mr. J. Mayo, of Palmeston, New Zealand, gave a lecture, principally upon fruit growing in that colony, where he was formerly government pomologist. Mr. W. F. G. Spranger, president of the association, occupied the chair. Mr. Mayo, in speaking of fruit cultivation in New Zealand, showed how the colonists studied the taste of the English people in growing fruit for the English market. He also mentioned how the New Zealand Government not only fostered industry but actually enforced proper attention being paid to the fruit trees. He afterwards spoke of the vineyards to be found in the colony, and of the cultivation of lemons.

Dr. Angell sent a number of dried specimens of New Zealand ferns which were of special interest on this occasion; Mr. E. J. Wilcox, gardener to Colonel Sinkins, Aldermoor House, exhibited a number of insects injurious to apple and pear blossoms; Mr. B. Ladhams, F.R.H.S., had a fine display of zonal pelargoniums. Votes of thanks to the chairman, lecturer, and exhibitors concluded the proceedings.

New Chrysanthemums.—In my recent notes on "New Chrysanthemums," page 823, 1897, a clerical error occurred, where the name Mr. J. Gleeson was given instead of Mrs. J. Glessner. As the latter is a very promising variety, it is important to make this correction.—W. H. LEES.

A HOUSE BUILT UPON THE SAND cannot have a permanent foundation; and the same may be said of every undertaking in life. Success, to have a permanent effect, must be built upon something solid, or it will crumble into ashes when seemingly within our grasp. The foundation of anything of value must be carefully laid, or it will soon become useless. This remark is particularly applicable in reference to our health, for if it is not firmly established through the blood being pure and the stomach in regular order, we are liable at any time to be fatally attacked by disease. Holloway's Pills and Ointment lay a foundation of good health which will be permanent and strong as a rock.—[ADVT.]

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS MAGAZINE, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning change of dates

Lime-wash on Walls.—G.W., Kenley: To ensure lime-wash sticking firmly to the walls you must mix the lime with a very large percentage of size, obtainable at any oil and colour merchant's, and use as little water as possible. If allowed to dry thoroughly this mixture will withstand the effects of syringing for a very long period.

Pruning Wistaria and Jasmine.—G. W., Kenley: Little pruning is necessary in the case of either Wistaria chinensis or Jasminum officinarum. In the case of the former, where growth is not necessary for filling wall space, it is a good plan to spur back the long and young growths, as this ensures abundance of flowers and prevents overcrowding. The work can be done either autumn or spring when the climbers are being attended to. Make room for strong young growths of the jasmine, and remove any that are old and worn out.

Streptocarpuses.—G. W., Kenley: The treatment of streptocarpuses after growth and flowering has past should consist in keeping them clean from green-fly, giving the temperature of a warm greenhouse, and keeping them somewhat drier than during their period of activity. As soon as the days lengthen considerably repot the plants, but do not give a large shift. Place near the glass in an intermediate temperature until growth is vigorous, admitting air on all favourable occasions, and finally growing and flowering the plants in a not too airy greenhouse.

Cypripedium spectabile.—A., Devon: This charming hardy orchid can be cultivated in pots, but it is usually much finer if grown in a moderately moist position in a sheltered and partially-shaded part of the garden. Plants can be obtained from any dealer in hardy plants, and good specimens should be procured for pot culture. A suitable compost will consist of one part each of loam, peat, and leaf-soil, with a good sprinkling of sand. Keep the specimens from frost, but do not force them or subject them to a high temperature. A cool greenhouse will suit them. Little, indeed scarcely any, water will be needed until growth commences.

SEED LIST
(Free on Application).

FEATURES.
Alphabetically arranged.
Best sorts, in heavy type, can be seen at a glance.
Probably the most explicit practical instructions for cultivation ever published.
Many hints and recipes for cooking and serving the various vegetables.
Directions for the storing and forcing of vegetables.
Medicinal qualities of many vegetables and herbs.
Prizes of £5, £3, two of £2, and £1 offered for Photographs of Horticultural Subjects (see page 2 of Catalogue).

THE LIST, containing 93 pages, and a profusion of illustrations, shows (A) What to Grow; (B) How to Grow it; and (C) What to Do with it when Grown; and has been described by an agent on one of the largest estates in England as a BOOK OF REFERENCE.

Another Customer, testifying as to quality, writes: "I should like to add that all the Seeds, &c., purchased from your establishment during the past 14 years have been of the very best quality, and have given great satisfaction."

MERRYWEATHER'S
63, LONG ACRE, LONDON, W.C.

Gutter-Plate for Span-roofed House.—G. R., St. Neots: When fully [illegible] the gutter-plate for connecting the two spans should not be less than fifteen inches wide by two inches thick. If the houses are heavy and the rafters overhang the gutter a good deal, it will be better to have even a wider plate, so as to ensure a gutter of not less than nine inches wide.

R.H.S. Examinations.—A. P., Exeter: There were one hundred and eighty-one candidates for this examination in 1897, and of these eighty-seven were placed in the first class; fifty-four in the second class; twenty-eight in the third class; and twelve failed altogether. The medallist obtained the maximum marks—300—and the marks obtained by those in the first class ranged down to 200; indeed, 200 and over is the qualification for first class; 150 to 199 for second class; and 100 to 149 for third class.

Seedling Primula.—C. F. J., Cophampton: The seedling primula sent is an extremely handsome one, and should certainly be perpetuated now that you have succeeded in fixing it. The frilling is very pretty and full, while the orange area is remarkable for its size and depth of colour. The only fault we could find was that on two of the flowers the white border was tinged with yellow, and so the contrast seen in the pure white and deep orange flowers was largely lost. Possibly, however, the discoloration was the result of age and packing. Our opinion is, of course, given only upon the individual blooms; if the habit of the plant be poor and the trusses weak then the variety is of little worth, but these being up to the average you have a good primula.

Best Vine for Associating with Black Hamburgh.—P. M. C., Hereford: In a house that would be started about the first of February it is easy to give Black Hamburgh a good companion. If a white grape is wanted I would, writes Mr. S. Castle, advise Buckland Sweetwater, a very handsome sweet grape which generally does well. A second white would be Fosters' Seedling—of stronger constitution than the first-named, and a sure heavy cropper, but the berries are smaller, and it always lacks the noble appearance of Buckland Sweetwater. Should black grapes be wanted a most useful rich-flavoured variety for table is Madresfield Court. Its colour is always, however, a difficulty, and sometimes cracking of the berries follows. Where, however, this variety does well it is worth all the care and attention that can be given it. As a reserve black grape I would have Alicante—this started as stated would be ripe at the end of July or very early in August, and would be a nice companion to Black Hamburgh and a very agreeable change at the dessert table. Grown under the same conditions the Alicante crop will always be the heavier and with also a better keeping quality. A more extended list of varieties could be given and some are of a very high character, but high cultural skill is required to grow them in their best form. With regard to those grapes that succeed best with Black Hamburgh in a late vinery, I presume that by having Black Hamburghs in a late house, the real need is a supply from vines up to Christmas. Undoubtedly the best white would be Mrs. Pearson, a most useful grape which improves by hanging. I find the vines very robust and hardy; it is free setting and in fact a good amateurs' vine, given fire heat. Alicante, again, should also find a home here, as there is none to equal it for late keeping, and it will succeed where the higher quality varieties would fail. Could Gros Colmar be put in the warmest end and lightly cropped the first ten years it will, with careful management, hold its own against all the others.

Phœnicoma prolifera Barnesi.—R. M., Littleham: The specimen should be kept during the winter in a temperature falling not lower than 45 degrees by night; a minimum of 50 degrees would be better, with a rise of five or more degrees by day in bright weather, taking advantage of warm days to admit air. Keep the plant near the glass. Early in April, if it is necessary, pot your specimen, but do not give too large a shift; for compost use good fibrous peat and plenty of sand. Afford ample drainage, and over the crocks place a thin layer of sphagnum moss. Potting may be deferred until after flowering, if such is thought desirable. Plenty of moisture will be necessary during the flowering and growing seasons, but much less is needed during the winter months. Flowers of phœnomas should not be allowed to remain on a specimen for more than six weeks; being somewhat of an everlasting character they are frequently left on, and so they materially weaken the specimen and reduce its chances of flowering the next year. Plants potted early will need to be shaded somewhat during growth on very bright days, but after August shading should not be necessary. Moderately strong growths may be inserted as cuttings during April; place them in sand and keep close, when they will root during the autumn and may be potted on the following spring. Your former question as to vines arrived too late for insertion in the issue you wished it to appear; we shall be glad to answer any questions relating to the subject.

Names of Plants.—G. W., Kenley: Epidendrum planilabris.

J. M. S., Bognor: 1, Sequoia (Wellingtonia) gigantea; 2, Picea Pinsapo.

J. S., Horsham: We had some difficulty in determining the specimen sent, but the receipt of your second one was of much assistance. The plant is Ruellia Portellæ, a good winter-flowering subject, but very little known.

E. F., Reading: 1, Meniscium simplex; 2, Davallia pentaphylla; 3, Polypodium rupestris.

M. T. A., Derby: 1, Thuiopsis dolobrata; 2, Eleagnus pungens; 3, Chimonanthus fragrans.

P. H. T., Swansea: 1, Cypripedium Harrisianum; 2, Aralia Chabrieri; 3, Pavettia borbonica; 4, Russellia juncea.

Names of Fruits.—S. C., Birmingham: 1, Besi Mai; 2, Winter Nelis.

E. F., Stockport: 1, Worcester Pearmain; 2, not recognised, but probably a poor specimen of Golden Noble; 3, Keswick Codlin; 4, Waltham Abbey Seedling.

D. W. P., Norwich: Glou Morceau, a good specimen.

M. B. B., Ludlow: 1, Lane's Prince Albert; 2, Fearn's Pippin; 3, Betty Geeson; 4, Norfolk Beefing; 5, French Crab.

S. S., Walthamstow: 1, Beurre d'Aremberg; 2, Catillac; 3, Josephine de Malines; 4, Round Winter Nonsuch.

L. C., Plymouth: 1, Bergamotte d'Esperen; 2, Beurre Rance; 3, Nouvelle Fulvie.

H. H. T., Ripley: 1, London Pippin; 2, Royal Russet; 3, Dumelow's Seedling; 4, Beurre Sterckmans; 5, Nec Plus Meuris.

MARKETS.

Covent Garden.

SUPPLIES of almost all kinds are shorter than usual, but as trade is dull prices have not been much altered. There is a good demand for best apples, good grapes, and nuts. There is a moderate cut flower trade.

FRUIT.—English apples, 4s. to 9s. per bushel; American and Nova Scotian, 15s. to 35s. per barrel; English grapes, 1s. 3d. to 2s. 6d. per lb.; Almeria, 12s. to 20s. per barrel; French pears, 6s. to 8s. per crate; 5s. to 6s. per case; pineapples, 2s. to 5s. each; bananas, 5s. to 10s. per bunch; pomegranates, 7s. to 9s. per case; Messina lemons, 10s. to 18s. per case; Valencia oranges, 8s. to 15s.; Denia, 8s. to 16s.; Murcia, 5s. to 8s. per case; Jaffa, 8s. to 10s. 6d.; mandarins, 9d. to 1s. 6d. per box; French chestnuts, 7s. to 10s.; Italian, 12s. to 15s. per bag; dates, 10s. to 12s. per cwt.

FLOWERS.—Arums, 4s. to 6s.; carnations, 1s. to 3s.; chrysanthemums, 6d. to 2s. 6d.; gardenias, 2s. to 5s.; eucharis, 4s. to 6s.; Lillium Harrisi, 4s. to 6s.; tea roses, 6d. to 1s.; pink roses, 1s. to 3s.; cattleyas, 6s. to 10s.; Odontoglossum crispum, 1s. 6d. to 4s.; and tuberoses, 3d. to 4d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; chrysanthemums, 3s. to 6s.; marguerites, 2s. to 4s.; mignonette, 2s. to 4s.; pelargoniums (scarlet), 5s. to 9s.; and violets, 1s. 6d. to 2s. 6d. per dozen bunches; azaleas, 9d. to 1s. 6d.; stephanotis, 4s. to 6s.; white narciss, 1s. to 2s.; Roman hyacinths, 6d. to 1s. 6d.; lily of the valley, 1s. to 2s.; and pelargoniums, 6d. to 9d. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 3s. to 4s. per bunch.

VEGETABLES.—Seakale, 12s. to 18s. per dozen punnets; celery, 9s. to 18s. per dozen rolls; horseradish, 12s. to 20s. per dozen bundles; English onions, 4s. to 5s. per cwt.; Valencia, 5s. to 6s. 6d. per case; Belgian, 3s. to 3s. 6d. per bag; eschallots, 2s. per 12 lb.; spinach, 2s. per bushel; turnips, 3s. to 4s.; carrots, 3s. to 3s. 6d.; parsley, 1s. 6d. to 2s. per dozen bunches; beetroots, 2s. to 3s.; cabbages and savoys, 3s. 6d. to 5s. 6d. per tally; cauliflowers, 1s. to 2s.; French endive, 1s. 6d. to 1s. 10d.; artichokes, 2s. to 3s.; lettuce, 10d. to 1s.; cucumbers, 3s. 6d. to 6s. 6d. per dozen; radishes, 10d. to 1s. per dozen bundles; mushrooms, 6s. to 9s. per 12 lb.; Brussels sprouts, 1s. to 1s. 3d. per half-sieve; potatos, 60s. to 100s. per ton.

Borough Potato Market.

Supplies continue to be light, but as the demand is small prices remain as previously.

Dunbars, 115s. to 125s.; Hebrons, 85s. to 105s.; Snowdrops, 85s. to 95s.; Bruce, Maincrops, and Sutton's Regents, 75s. to 85s.; Reading Giants, 75s. to 80s.; Saxons, 75s. to 80s. per ton; Belgians, 3s. 6d. to 3s 9d.; Germans, 3s. 9d. to 4s. per bag.

INDEX TO VOLUME XI..

NEW INVENTIONS.

Automatic Fire Alarm.—Pearson's automatic fire indicator is similar to Sixe's thermometer, such as is used to register the highest and lowest temperatures of the day. The usual mercury column is employed, but the thermometric fluid is pure creosote. This has the advantage of being a bad conductor of electricity and of preserving the mercury from oxidation—the trouble which usually occurs in thermostats of this design, and, of course, spoils the electrical contact. When, under the influence of heat, the mercury rises it covers two fine platinum wires fused into the glass about a quarter of an inch apart, and thus establishes electrical connexion between them. The instrument can be constructed to close the circuit at any desired temperature within certain limits, but for ordinary purposes it is generally set at about 110 degrees Fahr., such a position being selected in fixing it in a room as will be most quickly affected by increase of temperature. The platinum wires are connected to some signalling device, such as an electric bell, which may ring in the house or at the fire-station. The Pearson's Automatic Fire Indicator Company have also arranged to use the wires of the District Messenger Company, to whose nearest office an alarm would be transmitted. The fire insurance offices are said to look favourably on the apparatus, which is being used by several large firms, as well as at Woolwich Arsenal.

The mean reading of the Barometer during the week at Greenwich was 29·51 inches, and that of the Thermometer 45°·1, the latter being 6°·6 above the week's average in the 50 years 1841—90. The direction of the wind was south-westerly, the horizontal movement of the air being 58 per cent. above the week's average in the 16 years 1860—75. The duration of registered bright sunshine in the week was 5·0 hours. The measured rainfall amounted to 0·66 of an inch.

ENGAGEMENTS FOR THE ENSUING WEEK.

AUCTIONS.

MONDAY, WEDNESDAY, AND THURSDAY, JANUARY 10, 11, AND 12.—Border Plants, Roses, Fruit Trees, Shrubs, Lilies, &c., at J. C. Stevens's Rooms.

EPPS'S COCOA.

EXTRACT FROM A LECTURE ON "FOODS AND THEIR VALUES," BY DR. ANDREW WILSON, F.R.S.E., &c.—"If any motive—first, of due regard for health, and second, of getting full food value for money expended—can be said to weigh with us in choosing our foods, then I say that Cocoa (Epps's being the most nutritious) should be made to replace tea and coffee without hesitation. Cocoa is a food; tea and coffee are not foods. This is the whole science of the matter in a nutshell, and he who runs may read the obvious moral of the story."

GREATLY REDUCED RATES FOR LARGE QUANTITIES. *Full directions for use post free on application.*

EXTRACTS FROM SOME RECENT TESTIMONIALS.

MR. LEONARD BROWN, BRENTWOOD.
Hon. Sec. National Amateur Gardeners' Association.
2nd December, 1897.

I have used Jadoo Fibre with the best results possible for Ferns, Cannas, Arums, Hyacinths, Tulips, in fact for Bulbs of all sorts. I find the material most suitable for spring flowering Bulbs, as the pots get quite full of roots before top growth commences, a condition that goes a long way towards success. Lilies, too, have been particularly good; not only did they flower unusually well as regards both size and colour, but the Bulbs are in splendid condition for next season. I have also used Jadoo for propagating from seed and cuttings with good results, seeds germinating very quickly when sown on the fibre. I consider Jadoo to be of the greatest assistance to the Amateur, more particularly to those who are engaged in business during the day, as much less water is required, and consequently more time can be given to other work.

Important Certificate from DR. A. WALLACE, of COLCHESTER, *the well-known authority on Lilies.*

I have tried the effect of Jadoo on Lilies and Gladioli grown in the open garden during the past season, putting a small handful of Jadoo when planting round each bulb above and below.

On taking up the bulbs, which had flowered well, I found evidence of increased root action where Jadoo had been used, the roots being more numerous and larger, and often in lifting the bulb a mass of Jadoo came out also, grasped by the roots. I shall certainly persevere in the coming season with Jadoo, as I consider, so far, the experiment has been satisfactory. Some delicate Lilies, such as Krameri. Odorum, and Leichtlini, certainly made much better growth in it than usual, and, generally, the new growth in the futnre bulb was more thoroughly finished.

10th December, 1897. ALEXANDER WALLACE, M.D.

AWARDS — **Silver Medal, National Chrysanthemum Society, Westminster, November, 1895. Silver Medal and First Class Certificate, Durban and Coast Agricultural Society, Natal, 1897. NOTES OF THE WEEK.

A DESTRUCTIVE ORCHID PEST.

In several collections of orchids that have come under our notice within a comparatively recent period considerable damage had been done by an insect pest which has hitherto not been regarded by the general body of orchidists as an enemy with which they have to reckon in following their fascinating pursuit. A considerable number of species had been injured by the attacks of the pest, but the greatest sufferer was the Moth Dendrobium (*D. phalænopsis*), owing probably to the more delicate texture of the cuticle of its leaves than that of other occupants of the orchid house. The presence of some enemy of the plants was first indicated by the leaves becoming marked by yellowish blotches, and it was observed that as the blotches increased in number the plants became unhealthy, made but little progress, and in the case of severe attacks succumbed to the injury they had received. In one or two instances it was assumed by those in charge of the collections that the blotches had been caused by a fungus, but further investigation revealed the fact that, as in other cases, the mischief had been wrought by some form of animate life. By subjecting the plants to careful examination at night with the aid of a lamp, a diminutive insect was discovered busily engaged in feeding upon the juices of the plant. To discover the resting place of the pest was the next step, and in searching the material in which the plants were potted near the base of the pseudo-bulbs, both the perfect and nymphal forms of the insect were found in comparatively large numbers. The last-named of the two forms was met with in various stages of development, these being chiefly represented by the difference in the size of the rudimentary wings. With a plentiful supply of material there has been no difficulty in identifying the pest as Phytocoris militaris of Westwood, which has long been known to science, although, happily, not familiar to orchidists until quite recently. The insect, when it has attained its full development, is nearly a quarter of an inch in length, deep sanguineous crimson, with black or dark markings. The rostrum, or sucking apparatus is, relative to the size of the insect, of great length, and consists of a tube working in a case, and within the tube are sharp suckers, which penetrate the outer covering of the leaves and extract their juices. In the nymphal stage, the insect is yellowish, with black lines on the thorax, and black wing pads. It may be assumed that the pest has been introduced to the orchid house by means of imported plants, and it is therefore essential that these should be subjected to a close examination before they are placed with the general collection. The eggs are deposited on the pseudo-bulbs, but in consequence of their small size are not readily detected without the aid of a powerful pocket-magnifier. During the day the insect in its various stages takes refuge in the material in which the plants are potted, and before this fact was discovered those orchid growers who have had their plants attacked were greatly perplexed in discovering the cause of the unhealthy appearance of their plants. With regard to remedies, very little can as yet be said, as those suggested have hardly passed through the experimental stage. So far dusting with tobacco powder has not realised expectations, but spraying with quassia and soft soap in solution, and of a moderate degree of strength, has given very good results. Although the phytocoris has been very destructive in several collections, we do not regard it as so formidable a foe as to justify widespread alarm, but it is likely to prove very troublesome, where it is successful in obtaining a foothold, if repressive measures are not adopted immediately its presence is discovered.

METHODS AT FLOWER SHOWS.

Fifty years ago the late Mr. C. J. Perry, of Birmingham, was advocating in the columns of the GARDENERS' MAGAZINE the abolition of the old-fashioned system of numbering stands, collections, &c., at flower shows—a method adopted by our forefathers in the interests of secrecy, the names of the exhibitors in any form being withheld until after the awards were made, and then placed only on the winning stands. It was, and still is, in places where the old method is yet adhered to, a reflection on the judges, suggesting they would be liable to favour certain individuals could the ownership be made known to them. We find the old method still employed in many parts of the country, and at some exhibitions of considerable note. But it has its disadvantages. It entails a great amount of work on the secretarial department on the day of the show; considerable delay occurs in compiling a complete list of the prize winners; the representatives of the local newspapers, who are naturally desirous of giving a list of awards in full, are sadly inconvenienced; and there is the further disadvantage, alluded to above, that only a small proportion of the exhibitors—those taking awards—have their names placed on their exhibits, such publicity being their due, and one much sought after in local circles. It is, however, quite certain that the system of withholding names does not answer the end sought by its adoption. If there is a desire on the part of a judge to favour a certain individual there need be no difficulty in arranging some method by which the identity of the exhibitor may be made known, for wrongdoers are as fertile in device and resource as they who will be just and straightforward. There was a time when, probably, favouritism was shown, and when judges were suspected, and the secret system did not prevent it. In these days judges are not only selected because of the possession of known abilities, but also because men of position and acknowledged rectitude; their names are sometimes openly published in many schedules of prizes, and they have reputations at stake. The choice of qualified censors is much larger than it was a quarter of a century ago, and a judge who is known cannot now afford to be other than honourable. He may make mistakes, but they are errors of judgment and not the results of a determination to do wrong. It has been stated—no doubt more as an outcome of genial sarcasm than as an actual occurrence—that the old florists of two generations ago, in their feasting and talk after one of their shows, would always drink to the toast "May we never be fun' out"—a sort of humorous confession that they did play little tricks on each other, and especially on the judges. If there was ever a semblance of truth in the statement the old order has now changed to a new and better one.

NITRAGIN.

The new material introduced two years since under the somewhat unfortunate appellation of nitragin, for the purpose of inoculating the soil with nitrifying bacteria specially suitable for the several leguminous plants cultivated in garden and field, has failed in this country to realise expectations. The material, prepared by one of the leading agricultural chemists in Germany, after lengthened investigation, was intended to promote the growth of leguminous plants by promoting the formation of nodules on their rootlets which are so closely associated with the assimilation of nitrogen from atmospheric sources. The preparation was subjected to a careful trial by several experimentalists in Scotland, including the authorities of the Royal Botanic Gardens, Edinburgh, but the results were of a negative character. In one or two instances the Royal Agricultural Society was rather sharply criticised because the Council did exactly what it should have done, sent the society's consulting chemist to Germany to make inquiries as to the method of preparing the material, and its effects upon the crops, and then afforded facilities to those who desired to experiment with it to obtain small supplies. As a matter of course, an extended series of experiments were carried out with nitragin on the society's experimental farm at Woburn, and chiefly in the hope that it might prove a solution of the clover-sickness difficulty. In his report upon these investigations Dr. Voelcker states that though here and there have appeared some indications of success attending the employment of the preparation, nothing of a definite nature has been ascertained as the result of carefully conducted experiments. In conducting the experiments with beans, it was found that when the seed was inoculated with nitragin specially prepared for beans, the plants were in bloom eight days before the plants in the other plots evinced signs of flowering. The next plants to come into flower were those in the plot the soil of which had been inoculated, and the latest to bloom were the plants growing in the untreated plot. The acceleration of the period of flowering, however, was no advantage to the crop, for the precocious plants became stunted later on, and produced a lighter yield. From the experiments made at Woburn and elsewhere, it appears reasonable to assume that our ordinary garden and agricultural leguminous plants have no difficulty in finding in the soils of this country the organisms which they require for nodule development and nitrogen assimilation, and that we must continue to regard good tillage as the prime factor in the plentiful production of root nodules by cultivated legumes.

FRUIT AND VEGETABLE IMPORTS.

The Board of Trade returns for December last are somewhat unsatisfactory, for both imports and exports are below the totals of the corresponding month of 1896. There was a decrease equal to 5·2 per cent. in the imports; of 4·9 per cent. in the exports of British and Irish produce; and of 17 per cent. in the exports of foreign and colonial produce. These decreases are in the majority of cases due to a decline in value rather than to a reduction in quantities. The imports of fruits and vegetables were less regular than for several months past, and increases and decreases were almost equally balanced. As might have been expected by those who have paid attention to the reports of the American crop, there was a material decrease in the imports of apples, the aggregate quantities received having been 410,954 bushels, of the value of £131,870, against 1,186,464 bushels, of the value of £280,703 in December, 1896, or a decrease in quantity of 775,510 bushels, and in value of £148,833. The imports of apples for the twelve months was 4,199,971 bushels, of the value of £1,187,363, against 6,176,956 bushels, of the value of £1,582,495, in 1896. Pears, on the other hand, show some increase, for we imported 11,822 bushels, of the value of £6,342. The increase on the year was relatively much larger, for the aggregate imports were 1,057,694 bushels, and our bill for them amounted to the substantial sum of £371,808. For the first time plums have a place in the returns for December, and it is interesting to observe that 604 bushels were imported, and that their value is returned as £184. For the year the imports of plums were about 20,000 bushels less than those of pears, but their values ruled higher, as these closely approached half a million sterling. Grapes show a drop of from 7,422 bushels to 1,634 bushels, with a corresponding decrease in values, but for the year there was an increase of upwards of 100,000 bushels, the actual quantities received having been 995,413 bushels, of the value of £495,642. Unenumerated fruits continue to increase, and our bill for them in 1897 amounted to £695 404. As in November, so in December, there was a material augmentation in the imports of potatos as compared with the corresponding month of the two previous years. The total was 472,867 cwt., of the value of £82,096, against about 32,000 cwt., returned as of the value of about £6,000, in December 1895 and 1896. There was an enormous increase in the German supplies, and also in those received from "other countries." The imports of potatos during the twelve months ending with December last very closely approached 4,000,000 cwt., and the bill for them considerably exceeded £1,000,000. Onions, on the other hand, evinced a decrease both for the month and the year, and it is interesting to observe that there was a material recovery in values as compared with those obtaining in the two previous years. These figures are of interest, as they indicate our dependence upon foreign cultivators for immense quantities of fruits and vegetables that could be profitably produced at home.

Position of the Royal Botanic Society.—At the meeting of the Fellows of this society on Saturday, Major Cotton, who presided, referred at some length to the present position of the society. In the course of his observations, he stated that the year 1897 had been a very eventful one in the history of the society, and he was pleased to be able to congratulate the Fellows upon the very excellent position in which the society now stood as compared with its position at the opening of last year. At that time the outlook was gloomy, for the lease of the gardens was about to expire, and an accumulated balance of some thousands of pounds stood on the wrong side of the accounts, and was not only in itself a source of much uneasiness, but also prevented the society from giving prizes at the various fêtes and shows as liberally as it desired. The position, however, had been resolutely faced, and he was pleased to say that, with the co-operation of the council and some of the leading Fellows, the society was now perfectly solvent, and the accumulated debt, which had so long been a source of trouble and anxiety, had been swept away. A new lease for the maximum term of thirty-one years had been promised by the Commissioners of Woods and Forests, and it now only remained for the Fellows to use their utmost endeavours and to induce friends to make the society the success it should be. Not only were the gardens open for study to the pupils of the various medical schools, but a school of practical gardening had been started with the concurrence and aid of the London County Council. The Middlesex and Herts County Councils had approached the society with a view to sending students to the new school, and it was believed that to ladies also such an opportunity of learning gardening would be most agreeable. The council of the British Astronomical Association, too, were taking steps to erect and equip an observatory in the gardens. Reference was made to the great increase in the number of Fellows elected in 1897, there having been more than eighty above the average numbers of the last ten years.

A New Garden for London.—We are pleased to learn that a movement is on foot for the purpose of securing one more open space for perhaps the most crowded part of South London. A number of employers of labour in the district and some of the principal ratepayers have approached the London County Council with a view to that body acquiring, laying out, and maintaining the garden of Nelson Square, Blackfriars Road, as an open space. The garden is a large one, and the square is bounded on the east by a number of narrow lanes and courts. The only open space in the neighbourhood in which children can play with safety is the small garden in Red Cross Street, Borough. It is also hoped that the churchyard of Christ Church may also be converted into a garden before the coming spring, the rector being desirous of meeting the views of the vestry if satisfactory arrangements can be made for preserving order.

Victoria Medal of Honour.—The Council of the Royal Horticultural Society having been consulted as to a proper mode of the use of the Victoria medal by members of the trade, have decided that the only permissible method is by the letters V.M.H. following the name of the holder of the medal. No other mention of the medal can be properly made in any application pertaining to horticultural trade or relating thereto.

New Apples.—Messrs. Dickson and Co., of 1, Waterloo Place, Edinburgh, write: "Referring to your article and illustration on page 8 of the GARDENERS' MAGAZINE, on the new seedling apple, James Grieve, raised and sent out by us, a few additional particulars may be of interest to your readers. It is a seedling from Pott's Seedling, and in the habit, wood, foliage, and buds it has very much the same character as the parent. It fruited first with us in 1887. At the same time as we raised it we had a number of other seedlings from different well-known varieties, and those which in their wood, foliage, and robustness showed exceptional promise were selected and grown on for trial. One of those which we named, Bailie Neilson, a seedling from Golden Drop, has also proved a very valuable acquisition, and was awarded a first-class certificate at the International Show, Edinburgh, in 1891; this is a kitchen apple, with large fruit, an abundant bearer, and its season is from October to January; it is being largely planted by market growers. Although raised from Pott's Seedling, James Grieve has proved a very fine dessert fruit; it is much hardier than Cox's Orange, which in Scotland requires to be grown on a wall, while James Grieve fruits freely on standards. In Scotland the season for this variety extends from September till March, and it retains its juciness till the last. Some of the other seedlings raised at the same time as James Grieve and Bailie Neilson, and are heavy and constant bearers and of first-rate quality, are W. Robinson, James Welsh, P. W. Fairgrieve, Dr. Robertson, Malcolm Dunn, and Edinburgh Castle, and they should come prominently to the front when better known."

Injurious Insects in 1897.—In her annual report on injurious insects Miss Eleanor Ormerod observes with reference to those which attack the occupants of garden and orchard: Attacks to orchards and bush fruits are steadily increasing both in severity and in difficulty of dealing with them, consequently on the increasingly large areas of land occupied permanently by one kind of crop. Applications regarding apple attacks were unusually numerous, including those of codlin moth and sawfly caterpillars to fruit; weevil and the little "apple sucker" (*Psylla mali*) to the flower buds or their stems, and thrips also, and the apple bark scale. An attack to fruit in one district, which I was informed had been considered to be that of the exceedingly injurious maggots of the U.S.A. Trypeta pomonella, caused some uneasiness, but as no larvæ or specimens of the fly had been secured, I venture to hope it may turn out to be only a somewhat uncommon form of one of our English attacks. Anyway, it can do no harm to mention that if imported apples are noticed to be much tunnelled inside by the legless maggots of a two-winged fly, it would be of importance to attend to the matter at once. In plum-tree infestation I am sorry to say that yet another shotborer beetle has appeared, named the Xyleborus Saxeseni. Pear and cherry leafage is still yearly much injured by the caterpillars, known as "slugworms," of the pear and cherry sawfly, which is quite unnecessary, as the remedy and prevention of recurrence are sure and simple. The ordinary attacks to bush fruits appear to have been much as usual, excepting in a remarkable prevalence of the gooseberry and currant magpie moth, and also of the somewhat large "ground beetle"—the Harpalus ruficornis, which did much damage to ripening strawberry fruit in various localities, and appeared in great numbers, though (in the absence of strawberry grounds) not as a fruit pest, in the neighbourhood of St. Albans. The black currant gall mite, which causes the buds to develop into mere useless roundish knobs instead of producing fruit and leaves, now causes serious and yearly increasing losses where this crop is grown on a large scale, and the yearly repeated and carefully conducted experiments of some of our chief currant growers, have as yet failed in being more than palliatives. As, however, there appears to be just a possibility that some varieties might be less subject to attacks than others, I have, through the courtesy of one of my colleagues, been favoured with a supply of cuttings from Buda-Pesth, which will be carefully experimented with, and the result (if satisfactory) duly mentioned. Amongst attacks to root crops, and to roots of grass and corn crops, damage was, as usual, done by the wireworms and daddy longlegs grubs, also by maggots of cockchafers and rosechafers, especially by the last, for the ravages of which at grass roots no reasonably practicable remedy has as yet been brought forward. Amongst turnip attacks, diamond-back moth appeared at several localities late in the season, and attacks of a small weevil and a gnat midge maggot in the seed were present, also an unusual amount of damage was done to roots not much advanced in growth by "surface caterpillars."

"Garden and Forest" has been so admirably conducted from the first that we greatly regret to learn that with the completion of the tenth volume its publication has ceased. In announcing the discontinuance of the journal, the editor observes: "For ten years the experiment has been tried of publishing a weekly journal devoted to horticulture and forestry, absolutely free from all trade influences, and as good as it has been possible for us to make it. This experiment, which has cost a large amount of time and money, has shown conclusively that there are not persons enough in the United States interested in the subjects which have been presented in the columns of *Garden and Forest* to make a journal of its class and character self-supporting."

Potato Culture in France for the production of supplies for purposes of human food has steadily increased during the past thirty-five years. From the official returns recently published it appears that in 1862 there were 3,049,9 acres under potatos; in 1872, 3,304,398 acres; and in 1882, 3,641,154 acres. There has also been a material increase in the area under carrots, cabbages, turnips, and similar green crops for consumption by the people during the same period, which appears to indicate a larger consumption of vegetables in France.

Additions to Kew Gardens.—The Queen has given directions for the Kew Palace, which is situate on the north-east side of the royal gardens, to be opened as a public museum under the same management as the botanical establishment which has made Kew famous throughout the civilised world. The Palace meadow, some four and a-half acres in extent, and situate on the eastern side of the building, was added to the royal gardens early in the spring of 1895, and full advantage has been taken of the facilities it offered for providing a more direct road to the arboretum. The Queen has also expressed her pleasure that the Queen's Cottage which nestles amid the trees at the south-west corner of the royal gardens shall also be added to them.

Exeter Gardeners' Association.—The second-half of the current session of this society was opened on Wednesday evening last, when a paper on Himalayan Rhododendrons," by Mr. R. Gill, was read. The papers arranged for the subsequent meetings are as follows: January 26, "Culture of Cattleyas," by Mr. G. Lee; February 9, "Experimental Culture of Vegetables with and without Chemical Manures," by Mr. F. W. E. Shrivell; February 23, "Potatos," by Mr. W. R. Baker; March 9, "Variety in the Flower Garden," by Mr. J. W. Moorman; March 23, "Summer Bedding," by Mr. J. Abrams.

An Old-Fashioned Garden.—We tried an old-fashined garden in Schenley Park this year, says Mr. W. Falconer in *Gardening* (America). We needed a handy dumping ground, and hit on the head of a deep ravine between two woods; into it we dumped hundreds upon hundreds of wagon loads of rock and clay, filling it near to the top, then surfaced it with good soil. Here we planted some shrubs, and broadcast among them set our scarlet poppies, eschscholtzias, dwarf nasturtiums, snapdragons, pansies, marigolds, and all manner of hardy herbaceous plants, having enough of each sort to make a mass of its kind and colour, and the effect was fine. In the middle was a plantation of hundreds of clumps of Japan and German irises interplanted, thence succeeded by thousands of gladioli, and banded with montbretias, from which we had flowers till frost. The steep face of this hill was graded a little, and a series of winding stone steps set into it, making the descent into the hollow quite easy; the stones were the rough uneven slabs secured in blasting the rocks when grading in other parts of the park, and both outer edges of the steps and along the sides of the upper walk a wide belt of moss pink was planted. And the banks all about were planted with shrubs, vines, wild roses, columbines, and other plants. More cameras and kodaks were levelled by visitors at this piece of gardening than at any other spot in the park, and still we had acres of showy summer beds. It is pleasing to find that in America, as at home and elsewhere, picturesque gardening is appreciated by the general public, and the majority prefer it to geometrically-designed beds filled in a fanciful manner with gaudy summer flowers.

Asparagus Disease.—In his annual report for 1897, Mr. W. Carruthers, consulting botanist to the Royal Agricultural Society, states that in the course of the past year he received specimens of asparagus attacked by mildew from a district in which this vegetable is largely cultivated. For several years past the asparagus crop in the district has been considerably injured by the attacks of Puccinia asparagi, which is locally known as "the blight," and as the disease is steadily spreading growers are naturally anxious as to the ultimate results. The fungus appears in August and September, and by consuming the food stored up for the use of the asparagus it weakens the plant when it begins to grow in the spring, and seriously reduces the crop. It shows itself in blackish brown lenticular patches bursting through the skin of the stem and branches. These patches consist of a large number of microscopic seeds or spores, called teleutospores. They are the rest spores which preserve the plant through the winter; they remain dormant until the conditions in springtime cause them to germinate, at a time when the plants on which they live have sufficiently grown as to be ready for their attack. The rest-spore then throws out a tube which bears one, two, or three minute spores, and these quickly become ripe, fall off, and, resting on the asparagus, begin to grow, pushing a fine, sharp-pointed tube through the skin into the asparagus. The root or mycelium rapidly spreads in the attacked plant, and in time produces longish patches on the stem and branches, which ultimately burst through the skin and exhibit a large number of round orange-yellow spores. This stage corresponds to that which occurs in the barberry in the case of Puccinia graminis, the mildew of the wheat. All the stages of the life of the mildew of asparagus are spent on the asparagus, while in the wheat mildew the Æcidium stage is passed on the barberry. The mycelium, having got possession of the asparagus, produces in succession the three fruiting stages of its life, the first developing the yellow round spores of the Æcidium stage; the second the brown round or oval spores of the Uredo or rust stage; and the third the dark-brown oblong spores of the Puccinia or mildew stage. Each stage produces its peculiar spore, and each of the spores is able to enter and develop its mycelium in a healthy plant. Mr. Carruthers recommended that the diseased plants should be cut down at the level of the ground; that they should not be put into bundles, for the plants rubbing against each other would scatter the spores, but they should be carefully carried to a fire and burnt. In this way would be destroyed myriads of spores which would have reproduced the malady next year. It was desirable to get this done throughout the district and at once, for one diseased field or plot left in the diseased state would supply sufficient spores to infect the whole district next spring. It was further suggested that, as the disease had been so prevalent for some years, next year's crop should be several times sprayed with sulphate of copper or with Bordeaux mixture. This application would prevent the spores produced by the rest-spore from germinating on the surface of the plant, as well as the spores produced in the first two stages of the life of the fungus.

Gardeners' Royal Benevolent Institution.—The Duke of Portland has fixed Wednesday, June 8, as the date for celebrating the fifty-ninth anniversary festival (sixtieth year) of the Gardeners' Royal Benevolent Institution at the Hotel Metropole.

Railway Station Gardens.—The North-Eastern Railway annually offers prizes to the value of £200 for the best-kept gardens at the stations on their system. Last year the money was divided into twenty first, twenty second, and fourteen third prizes. The scheme has had the desired effect of stimulating the pride of the officials in charge of the stations, many of which have in summer been beautiful in their wealth of floral decoration.

Botanical Survey of India.—The report of the director of the Indian Botanical Survey for 1896-97 includes reports from all the directors of departments with the exception of that of Southern India. The results of the botanical exploration, by Lieutenant Pottinger, of a portion of the valley of the Irrawaddy, a country hitherto absolutely unknown, will shortly be published. A synopsis is given of the flora of Western India as far as the Tiliaceæ.

Iris Purdi.—In the proceedings of the California Academy of Sciences Miss Alice Eastwood, curator of the herbarium of the academy, figures under the name of Iris Purdl, the beautiful iris common in the Redwood region of Mendocino County, which hitherto has been confounded with Iris Douglasiana. It resembles the last-named species in its narrow, red-based, lanceolate spreading leaves and cream-coloured flowers; but differs from it in its larger flowers, in its lighter green, less distinctly nerved, stiffer and often glaucous leaves, broader stamens, and shorter, broader, capsules. This iris has been successfully flowered by Max Leichtlin in his garden at Baden-Baden, and is named in honour of Mr. Carl Purdy, of Ukiah, who first noticed and called attention to its peculiar characteristics.

Presentation to Mr. G. P. Miles.—The opening meeting of the Chester Paxton Society's winter session was held in the Grosvenor Museum, Chester, on Saturday evening last, under the presidency of Mr. Barnes, when the opportunity was embraced of presenting Mr. G. P. Miles, the hon. secretary for the past eight years, with a gold watch and chain, as a grateful expression of thanks for the invaluable services he has so willingly given to the society during this time.

Scale Insects and Their Enemies.—Mr. Frogatt, who has made many investigations in connection with various insects, recently exhibited at a meeting of the New South Wales Linnean Society a twig of a eucalyptus, on which was a colony of Leathery scales (*Eriococcus coriaceus*); among these latter had been placed the eggs of Thalpochares coccophaga, a scale-eating moth. The scales were themselves infested with the larvæ of a small black ladybird (*Cryptolæmus Montrouzieri*). Both the moth and the ladybird are useful in the destruction of scales, the former attacking and eating the detestable olive scale. The species of ladybird referred to is now bred in New Zealand and America for the purpose of combating scale insects on fruit trees.

Flower Belts.—One of the latest Parisian fashions in relation to the use of flowers for personal adornment, is the wearing of belts of flowers. The majority of the French ladies prefer belts made of Parma or Neapolitan violets, small roses, or pansies. The belt is completely covered with the flowers, which are sewn thickly together on a plain band of silk elastic, great care being taken to use the finest silk of exactly the same shade as the flowers chosen.

Grape-Keeping in New York.—In explaining the long-keeping qualities of New York state grapes, an American contemporary says that grapes, apples, and other fruits grown in Western New York have superior keeping qualities, due to the soil and climatic conditions. Grapes grown on clay-land are firmer and ship better than those grown on gravel. In Ohio an association known as the Claygrowers' Association handle only grapes grown on clay-lands. The three sections in New York where grapes are grown to the greatest perfection all lie near large bodies of water, an influence favourable to keeping qualities. Of the long list of varieties cultivated in this state the best of the long-keeping kinds are Catawba, Diana, Isabella, and Vergennes. To insure keeping they must be carefully handled; it is also important that the temperature be gradually reduced from the vines to cold storage, and there must be no sudden changes. The grapes should be left out-of-doors in crates the night after they are packed; early in the morning they should be removed to a cool building or dry cellar; then to a still cooler room adjoining the storage-room, and here the temperature should gradually fall until the desired point is reached. New York grapes intended for exhibition at the World's Fair were placed in cold storage November 1, 1892, and held there until spring, when they were shipped to Chicago in time for the opening of the Fair, May 1. The main supply was then placed in the cold storage building on the exhibition grounds. This building was destroyed by fire on July 12, and the reserve stock of grapes was lost; otherwise New York grapes would have been on exhibition every day of the Fair. As it was, but fifteen days intervened between the last showing of cold storage stock and the arrival of new-crop grapes. Catawba grapes are offered at reasonable rates in the markets of New York as late as April.

Presentation to Mr. C. Martin.—At the monthly meeting of the East Cowes Horticultural Association, Mr. C. Martin, head-gardener at Clarence House, was presented with a gold albert chain and medal attached as a token of regard and esteem and appreciation of the valuable services he had rendered the society. The medal bore an appropriate inscription.

"**Weather Influences on Farm and Garden Crops,**" will form the subject of the presidential address to be given by Mr. E. Mawley at the annual meeting of the Royal Meteorological Society to be held on Wednesday next. The lecture will be illustrated by lantern slides. As usual, the meeting will be held at the Institution of Civil Engineers, George Street, Westminster; and the chair will be taken at 7.30 p.m.

Chrysanthemum Conference at Orleans.—The issue of *Le Chrysanthème* for November and December, which has just come to hand, is of special interest, inasmuch as it contains a full report of the conference held at Orleans in November last under the auspices of the Chrysanthemum Society of France. The whole of the details of the gathering are given; the viands served at the banquet being fully set out.

THE LATE MONS. JEAN LINDEN.

FULL of years and honour, Mons. Jean Linden passed peacefully away early on the morning of Wednesday, the 12th inst., at his residence in Brussels. It is given to few men to so completely attain their highest ambition as the famous Belgian explorer, botanist, and horticulturist, has done. The best years of his youth were passed amid solitudes and virgin forests, in Brazil, Mexico, Cuba, Venezuela, Columbia, Guatemala, and Jamaica ; to his untiring energy and persistence, we are indebted for the introduction of many of our finest orchids and fine foliage plants. Born in 1816, Jean Linden was educated at the Faculté des Sciences of the University of Brussels, where he was one of the earliest of students. Acquiring knowledge rapidly, and showing a remarkable taste for natural history in all its branches, but for botany in particular, he was, at the early age of nineteen, entrusted by the Belgian Government with a scientific mission to South America, having, as colleagues, MM. Funck and Gheisbright. They arrived in Brazil at the end of 1835, after a three months' journey, and succeeded in two years in obtaining wonderful collections of varied sciensific interest. After this, M. Linden visited Yucatan and North Guatemala, experiencing considerable difficulties, owing to revolutions then in progress. Fever kept him a long time at Guadaloupe, but in 1841 the traveller returned to Belgium.

The same year, however, the travellers returned to Columbia and discovered Odontoglossum crispum, now possibly the most popular and widely-grown of all orchids ; other species were also found by him, but they are too numerous to mention here, suffice it to say that Jean Linden led us to understand the beauties of odontoglossums and cattleyas. He discovered and made known the wonderful mountain floras of the Cordilleras, and, in the province of Merida, he crossed the Paramo de Macuchies at an altitude of 13,000 feet, no mean performance at that, or even a later time. He subsequently explored the New Granadan provinces of Santadar, Soto, Socorro, and Velez, reaching Bogota, a famous orchid centre, in October, 1842. The basin of the Rio Magdalena was examined, and to cross the river he had to swim the whole distance, about one hundred and ten yards. Tolima, the highest point of the Eastern Cordillaras in New Granada, M. Linden ascended early in 1843 ; many weeks were spent in high latitudes, and the virgin forests of Quindiu were explored by him. Later in the year he went to Caracas, and subsequently explored in a very thorough manner the Sierra Nevada of Santa Marta, reaching the summit, 14,766 feet, after surmounting immense difficulties. Not satisfied with all these achievements, the intrepid explorer penetrated into the interior of Goajira, then inhabited by cannibal Indians. After a short period at Jamaica, M. Linden passed on to Cuba, and there spent six months in scientific exploration. In 1844 he left Cuba for the United States, and reached Belgium in October, 1845, after practically ten years spent amid the forests and mountains of Southern and Central America.

After completing his travels M. J. Linden commenced business as a commercial horticulturist, at Brussels. Here his wide knowledge of plants obtained in their native habitats ensured him a large measure of success ; he was also able to direct the travels of young men of enterprise who were willing to visit America and bring home plants of various kinds. His position as Consul-General also kept him in touch with the land he had spent so long a period in exploring, for besides success in business, M. Linden obtained very high commendations and appreciation from the Belgian Government, which he so long and ably served at the risk of his life. On the Continent Mons. J. Linden did much to induce a rational system of cultivation for what we now call cool orchids. The earliest imported odontoglossums were throughout Europe killed by much kindness, but the new culture commenced, and in 1863 Weir, Blunt, and Schlim found themselves on the same steamer bound for New Grenada and after cool orchids, chiefly Odontoglossum crispum. These collectors represented respectively the R.H.S., Messrs. H. Low and Co., and Mons. J. Linden. In later years the subject of this notice has been best known in his connection with L'Horticulture Internationale, at Brussels, a huge business carried on, or chiefly, under the direction of himself and son,—M. Lucien Linden. Two or three years ago, however, M. Linden père retired somewhat from the government of the concern, but we believe he retained the control and direction of the large staff of collectors up to the last. When long past the allotted three score years and ten, M. Jean Linden was hale and vigorous in mind and body. A more genial gentleman it was impossible to find, and as he retained in a wonderful manner the vivid impressions obtained in his youth, it was a real treat to hear him discourse upon the vegetation and geographical conditions of South America.

As a nation, Belgium mourns M. Linden for his wide discoveries ; as a city, Brussels mourns a lost citizen who has ever given to her his best services. The wide world of horticulture and botanical science feels deeply the loss of one of its ablest and earliest pioneers, and joins in sympathy for those whom death has so recently bereaved. We, on behalf of the readers of the GARDENERS' MAGAZINE, tender to Mons. Lucien Linden and other members of the family, that sympathy which also they will receive from horticulturists throughout the world.

Herbaceous Phloxes from Seed.—I do not know whether any seedsman offers seeds of these hardy plants in packets, but certainly anyone procuring good seed of the fine new varieties will assuredly get a good return for the small outlay incurred, by securing some fine showy seedlings. Hardy phloxes do not seed freely, and they are very easily increased through the agency of cuttings taken from the spring shoots or from side shoots in the autumn. The former will make strong stems, and carry fine heads of bloom the first year ; the latter roots then throw one or more shoots to bloom the following year. But when seed can be obtained, it is well to sow it early in the spring, and because it is rather hard-shelled, should not be kept in a place that is very dry. If sown in a pot or pan of soil, and stood in a gentle warmth, being kept just moist, growth may ensue in some three weeks. Because of the comparatively hard nature of the wood-growth, damping gives little trouble.—D.

MARKETING ORCHARD FRUIT.

I WAS glad to see in your issue of December 18 last so much space devoted to Mr. Garcia's important paper read at the Horticultural Club, and also your leader on the subject, as it points to the time when the trade portion of the horticultural world will be recognised as forming a part of so important a whole. I was also glad that Mr. Garcia referred to the question of non-returnable empties for apples and pears, and that his views so closely agreed with my own, although taken from a different standpoint, for although we belong to the same market, I was as ignorant of the contents of his paper as any member present. This opinion being gained by his great experience in handling fruit from all parts of the world, and not as particularly interested in the sale of homegrown, is to my mind the more valuable. Considering the acreage of new orchards, the very first year we have anything like a full crop, the importance of what we both advocate will be manifest to all connected with the trade. There is an old saying, "The nearer to church, the farther from God," and I think this sentiment is applicable to the bulk of our orchard fruit growers (outside the Middlesex market gardeners, who sell their own), as they are close to good markets and do not take proper advantage of them, but allow others 7,000 miles away to step in before them and put on the market a more saleable article, even if the quality is not so good.

This week I have had a letter from an apple grower in North Carolina advising apples, and saying he was given to understand that our customers now liked them in 40 lb. cases, each fruit wrapped in paper, and that if that was so he should send all his in future in that way, although it was a little more trouble and expense in packing. Mr. Garcia remarked that if our orchard growers had taken the care that tomato and grape growers had done, the foreigners would not have had the chance they now have. I am sure the outlook for the home produce was dark enough some years ago, and it only pays now if done on business lines adopted by our market growers. They acknowledged the difficulties and the opposition of importations, especially in cucumbers and tomatos. But an Englishman is hard to beat when he once sets himself a task, and our home growers were determined to keep pace with the foreigners by growing the best quality and packing in the best possible way, with the result that they have not only held their own, but to some extent have turned the tables on their rivals, as I have daily orders from Hamburg, Berlin, Stockholm, and other continental centres, as well as weekly from America ; so that English grapes, tomatos, and cucumbers are now sold in nearly every large market in Europe, and grapes in the principal cities of North America ; while on the other hand it is only the best varieties well graded and packed that will now pay to send here from abroad—the common Dutch cucumbers and Lisbon tomatos being a thing of the past ; yet this has been done in articles which bring much less than they used to do, while Mr. Garcia proved that good orchard fruit makes more now than it did forty years ago.

I persuaded one large grower who attends the market and sells his own to try cases for his apples this year, and he had ten thousand cut up ready to put together, and is quite satisfied with the result—as he found at the market that customers gave them the preference, and he could sell more readily than his neighbours with similar fruit in baskets. The great strength of the system being that it suits the buyer best, every large buyer I have spoken to on the subject say they would gladly give more for the fruit if no further trouble with the empties was involved.

I was pleased to hear Mr. Veitch, on behalf of the Royal Horticultural Society, ask Mr. Garcia to give his paper at our autumn meeting of the Society ; but as that will be too late for this year, I thought it best to try and drive the nail a little further home by trespassing on your valuable space, for I feel strongly that if the matter is left till we have the fruit ripening on the trees in anything like a crop, there will be woful waste, simply from the fact that it will be impossible to find empties sufficient to convey them to market, unless we adopt the popular method of the cider country, viz., the "sack."

Covent Garden. GEORGE MUNRO.

Changes in the Colours of Flowers.—It frequently happens that the colours of flowers produced late in the season by plants growing in the open differ materially from those developed under normal conditions, and in reference to these changes Mr. E. Hughes Gibbs observes in a contribution to *Nature*: "I venture to send you the following observations on the tendency of flowers to revert in colour when blooming out of season. We have had little frost here, and many flowers which are ordinarily out of bloom at this season still persist. The changes, however, in their normal colours are in some cases very remarkable. The red cactus dahlias are blooming almost orange, the outer florets being often nearly yellow. These dahlias are also, in many cases, showing a tendency to revert to the single form. A species of tropæolum, normally vivid scarlet, is blooming in a cool greenhouse, where air is kept on, and has in some cases reverted almost to clear yellow ; a streak of red down the centre of the petal being the only remains of its normal colour. In both the above cases I note that the edges of the petals are the first to change. A species of myosotis, ordinarily of a deep and very vivid blue, is flowering now a clear rosy pink, without the least tinge of blue. The flowers are well opened and normal in size. Lastly, a pure white phlox of dwarf habit shows a tendency to revert in some of its blooms, though not in all, to a greenish yellow hue. Such cases are probably common ; but it is with the feeling that they may point to climatic conditions as influencing the coloration of flowers, and as having, possibly, borne a large part in the gradual evolution of their respective tints, that I venture to record them." In some instances, as observant cultivators are aware, a high temperature will also have the effect of materially changing the colour of the flowers more particularly in the case of some of the chrysanthemums and tropæolums. Chrysanthemum blooms that are suffused with red or bronze upon a yellow ground, will when developed in a comparatively high temperature, become bright yellow. Some years ago we propagated a tropæolum with flowers of a rich chestnut colour in the autumn, and the greater proportion of the flowers produced in the propagating pit were deep yellow. In the spring when the plants began to bloom the flowers were yellow suffused with deep red, but when planted in the flower garden they assumed their normal hue

The Reading Primulas and Cyclamen.

The value of first-rate strains of primulas and cyclamen to gardeners who have conservatories to keep gay early in the year, and to supply demands for large quantities of cut flowers during the same period, is so obvious that it needs no discussion. Good strains are a necessity, and when a gardener can visit the nursery of a firm of seedsmen and there see magnificent varieties of these, grown wonderfully well, true to name, and from which seed will subsequently be supplied, he feels he is making no mistake in growing such sorts himself. Certainly at no one period have the Messrs. Sutton and Sons, Reading, a finer display than in January; but to fully understand the beauty and usefulness of the Reading primulas more than one visit is necessary, as most of the giant forms are late in flowering, and do not display to the full their charms until March or April, and this is especially the case with the brilliant and effective form known as Giant Crimson; in its case the early flowers that nestle amid the foliage are of a purplish hue, and not to be compared with the dark-eyed glowing flowers produced in fine trusses at a later date.

Something like eight houses at the Portland Road Nurseries are filled with primulas in about thirty varieties, and these are arranged in batches of contrasting colours, so that the effect is very fine. A view obtained through the whole length of one house of three divisions, and containing about two thousand four hundred plants is one not soon forgotten; and yet this is but a part of the feast, for not less than six thousand plants will come under the notice of a visitor who makes a point of seeing all he can. The Star primulas are particularly elegant, and the pure white variety, with its two-storied spikes of dainty blossoms, very forcibly reminds one of falling snow. No sense of cold is, however, experienced, for the bright rose-coloured form occupying the opposite stage provides a corrective. There can be no question as to the general utility of the Star primulas; they are elegant, bright, easily grown as annuals or biennials, continue in flower for a long period, and do not drop their flowers so readily as some of the more highly-bred sorts. Very many trials have already been made, with a view to producing this form of primula in other colours than rose and white, and some amount of success has already attended the efforts of Messrs. Sutton and Sons. It is a difficult matter, however, for the influence of varieties of the Giant and other strains, having distinct hues, is mostly seen in an enlargement of the starry flowers, and a reduction of quantity; this, of course, is of no value, for it spoils the effect of the Star primula. However, by cross fertilisation and selection new colours are being produced, though those colours are often absorbed by the seed parent, and do not fully appear for two or more generations. Incidentally it may be mentioned that a two-year-old Star primula, in a twenty-four-sized pot carried twenty-one spikes of flowers; many of these spikes were four stories high; that is, they had four tiers, and such spikes carried from twenty-four to thirty-six blooms each. This will give a very good idea of the usefulness of Star primulas for conservatory decoration. As a market variety there is no doubt a great future for this plant.

Giant Primulas at Reading.

Turning to varieties that appeal more to the eye of the florist, one is confronted with a remarkable variation of colour in flowers and foliage, while the leafage varies and is either plain, fern-leaved, or moss-curled in form. A batch of Gipsy Queen comes early under notice; this is one of the most distinct forms and an old favourite. Even as a foliage plant it would command attention, but when to handsome and dark-coloured fern-like leafage is added trusses of large, beautifully-fringed and purest white flowers, then the combination causes it to be one of the most handsome of primulas. Reading Blue is a grand companion for any white variety, its shade of colour being so distinct; it forms a suitable successor to Fern-leaved Blue, a variety similar in colour and form but fully a fortnight earlier in flowering, and with fern-like foliage. Another fern-leaved variety of exceptional excellence is Rosy Queen, and one of which there is a stronger stock than usual; the original stock of this variety was showing signs of sterility, so, as it was still in demand, a new one had to be raised; this has been done, and the result is a beautiful primula with light leafage and fine trusses of rose-pink flowers. The new and stronger type is, however, a little later than the old form. Sutton's Pearl is so well known and its white flowers so much admired that nothing further need be said of it. Coming to varieties of more brilliant hue there is nothing to exceed the dazzling glow of Brilliant Ruby, especially when some hundreds of plants are in first-rate condition, as at Reading; the name of the variety is admirably descriptive of the colour, while in form it is a pattern primula. Reading Scarlet commences to expand its trusses of deep scarlet flowers about Christmas-time, and is a variety much appreciated for association with Roman hyacinth and similar winter flowers; it also continues to provide a display over a period of about six months. Brilliant Rose cannot be passed unnoticed, for it never fails to attract attention, its large blooms are exquisitely frilled and of a beautiful deep shade of rose that eventually deepens to carmine; scarcely any variety appeals in so subtle a manner to one's sense of colour as does this. Royal White, Snowdrift, and Purity are all handsome white-flowered primulas, yet each distinct; it is no easy task to say which is the better, but the contrast of dark foliage in the former leads us to admire it the most.

A few remarks must be devoted to the Giant primulas, a distinct race produced and perfected by Messrs. Sutton and Sons, so distinct in fact that if any of its forms are crossed with the other single types, the result is usually sterile progeny. It is extremely difficult to fix and raise a sufficient quantity of any new giant form to put it into commerce. Nature protests against such huge flowers, wonderful frills, and fine trusses, by reducing the fertility of the plant. A handsome Giant Rose form tinged with crimson, has long been in course of selection, but during the past six years it has only been possible to double the number of plants. No giant primula has yet been returned as the result of pollinising a giant with a smaller form. As a race the Giant primulas are three weeks later than others, and for this reason they are worth cultivating; they also make larger specimens. Giant White is the most popular of all, and in either the plain or fern-leaved form it produces flowers of the purest whiteness, measuring twice as much in diameter as half-a-crown; the trusses are of immense size, and boldly placed above the foliage. Giant Pink runs the former very close for popularity, and because of its most vigorous growth is a prime favourite with the gardener; it also is earlier than Giant White, and a batch is already making a good exhibition of carmine pink flowers. Giant Crimson, as already stated, is a late form, and in some gardens lateness is considered a defect; however, once the variety is grown it is not generally left out of the next seed order. There is some hope, however, of an early giant of rich colour, for a moderate stock has been produced of a variety as early as Giant Pink, and producing glorious blooms that are of an intense rose-red colour, flushed with crimson. Double primulas are excellent, and give an abundance of large blooms admirably suited for wreaths, bouquets, &c.; for general use they are invaluable pot plants, and being presented in such a variety of colours as scarlet, blue, pink, carnation-flaked, crimson, and last, but not least, a magnificent white, there are sufficient kinds to gratify all tastes.

The Reading cyclamen were never finer than now, and that is saying a good deal. One scarcely can say just where the improvement occurs, but on entering the houses the impression quickly comes that plants and flowers are an advance on previous years. There is a wonderful wealth of blossoms, and on their sturdy stems they are not unlike batches of butterflies hovering above the marbled foliage. A slight but pleasing fragrance fills the air, but this emanates from a small batch of Cyclamen latifolium (C. persicum) raised originally from seeds sent from Palestine; fifty or sixty years hence Messrs. Sutton and Sons may have a giant form to show the horticultural world as the result of careful selection from this specific form. From the ten varieties of cyclamen listed by the Reading firm it is necessary for many to make a smaller selection, and as an assistance to that end we may say that the five appealing most to us are Giant White, White Butterfly, Vulcan, Salmon Queen, and Giant Purple. Giant White has monster, but not monstrous, blooms of infinite purity, and produced with wonderful profusion. White Butterfly has elegant white blooms, less formal than in Giant White but equally useful and produced in immense quantities. Vulcan is the finest of crimson cyclamen and is of a very deep and dark shade of colour. Salmon Queen is one of the Reading firm's greatest successes, especially so far as the production of new colours goes; the plants are dwarf and compact, foliage very finely marbled, and flowers of good size and of a handsome and rich shade of salmon-pink. Giant Purple is very distinct, and its bright purple blooms, though large, are carried erect on extra long and stout stems. A variety known as Giant Crimson and White has white segments with crimson base; the colour contrast is so fine that not a few would place it in a selection of five varieties, to the exclusion of one of the whites; it certainly is very beautiful. Giant Pink, Giant Rose, Giant Crimson, and Cherry

Red give flowers whose colour is well described by the name of the variety, and where large supplies of cyclamen are a necessity, and diversity in colour is desirable, it would be found that the varieties are all charming. Tastes differ so much that any selection made by one person would not suit all, therefore we may add that the Portland Road Nurseries are open to all flower lovers, and, the plants not being for sale, no one is asked to buy. Besides the foregoing there are numbers of curiosities in cyclamen, such as crested forms, papilionaceous forms, fringed and plain; some like single cactus dahlias, and others with double the usual number of segments. These all add to the interest of a visit.

WINTER BROCCOLI.

OUR winters are so uncertain, that the broccoli crop is not safe after the present. It is, however, to the mid-winter supplies, available from November to March, that I wish to refer, for it often happens the earlier broccoli are so far matured, that by lifting them the crop may be saved. The heads may be small, but they are valuable, and a welcome addition to the mid-winter supplies. To have a quantity of broccoli it is necessary to sow at different dates, and this is a matter I must dwell upon briefly. To make one sowing, say in March, and leave the rest to chance, will end in certain failure. It is not wasteful to sow several times; indeed, the reverse, as by sowing thinly much better plants are obtained, and the seeds required for several sowings are not more numerous than for one large sowing. In the latter case plants are so much crowded, that it is impossible for them to produce the best results; they are left too long in the seed bed and become exhausted. Of late there have been some really fine additions to the early broccoli. For many years the Cape varieties were the kinds mostly grown, but they were none too hardy, and the advent of Snow's Winter White was hailed with delight by all who needed this vegetable in quantity; having a hardy constitution it became a general favourite, and was so for a long time, but for the last year or two I have been obliged to discard it, not, however, until I had tried every means to produce it as good as formerly. Snow's, in my case, instead of giving good winter broccoli, was extremely uncertain, for some of the plants gave heads in April with late varieties. Mine was not a solitary case, so I naturally came to the conclusion it had become mixed with other sorts, and needed re-selecting with care. It was a grand broccoli, and its pure white compact heads during December and January were much prized.

Latterly Veitch's Self-protecting has taken the place of Snow's Winter White, and it is a splendid broccoli, but needs care in sowing to obtain it late; by this I mean sowing specially for late use. We make two sowings or more according to the season; sown in May or even early June in sheltered spots the plants will furnish the January and February supply, but seed must be sown thinly to produce sturdy plants. There also must be no starving in the seed beds, but plant them out as soon as the seedlings are large enough, and protect them in winter. Many may object to any variety not hardy enough to hold its own unaided; the plants are hardy, however, but the flower or head suffers. Our plan is to lift all plants with heads the size of a cricket ball and smaller and store them in open sheds, or what is better, in frames, so they may be used as required. The plants keep for a month or six weeks if treated thus, and there is no difficulty in obtaining a supply in severe weather, for this variety forms heads from October well into the autumn; indeed, I have had it good well into February, and with us it never fails to turn in.

Our selection to follow the last named is less known, but a specially fine type of early broccoli, not unlike Snow's in build and quality, but a true stock, as it turns in at one season from late January to early March, or gives the February supply, and is therefore invaluable. The variety in question is Sutton's Superb Early White, not a large broccoli, but one of perfect shape, compact, pure white, well protected by foliage, and having a dwarf stem it is rarely injured by frost. Much importance attaches to the build of a winter broccoli, for a dwarf compact grower tides over our variable winters better than larger kinds, and if with ample folding foliage there is also protection from rains and frost. This variety sown, if in April, will give good heads in January and February; but to have heads extra late I find the end of April a suitable time to sow for June planting, as it is essential to have strong plants for winter use. This variety if lifted and stored remains good for weeks; indeed I have kept heads over a month firm and good. To follow this variety our most reliable stock so far has been Veitch's Spring White, and this with us is far more reliable than the Penzance Early White, and also earlier, for it comes into use at the end of February, and, though not large, is just the size needed in a private establishment. It is a great gain on many of the older kinds, which are erratic in their season and larger in growth. Spring White is well protected by foliage, and very hardy; we usually plant it on quarters cleared of Early Ashleaf potatos or other early vegetables, and it needs similar treatment to that previously advised. We sow it the end of April or early in May, but do not plant it in rich ground; indeed, our best heads have been grown on land cleared of early strawberry plants, neither dug nor manured in any way, but merely hoed over and drills drawn to ensure the plants the moisture needed in dry summers. So far I have not lost many plants of either Superb Early White or Spring White. These are distinct varieties, and must not be classed as one. Spring White is the latest. With reference to losses, I mean losses in other seasons, for this year and season the plants look most promising. There may be other broccolis well worth special notice for winter supplies, but, after a trial of several, I find those named first-rate on account of their hardiness and reliability for difficult seasons.

Syon Gardens. G. WYTHES.

The Rabbit Plague in Scotland.—In the western highlands, where an [illegible] area has for a long period been devoted to game preservation, the rabbits have multiplied so freely that they threaten to become a serious plague. Trapping or shooting has not been done on any extensive scale, but hawks, falcons, owls, and other birds of prey have been persistently destroyed, until the rabbits have scarcely any natural enemies.

NOTES ON ORCHIDS.

ODONTOGLOSSUM RETUSUM.

A SMALL-FLOWERED species with orange-coloured sepals and petals and a yellow lip. It is not of any special horticultural value, although the branching spikes and numerous bright flowers would be effective if a batch of plants were flowered at one period. The colour of the flowers is particularly striking and the species should recommend itself to all lovers of orchids who find room in their collections for other than the showiest members of the order. Odontoglossum retusum has been imported by such leading firms as Messrs. F. Sander and Co., St. Albans; Messrs. J. Veitch and Sons, Chelsea; and Messrs. Linden and Co., Brussels; but it is probable that but few plants are purchasable; Hartweg was the first to discover it, and the find was made in 1841, on the Saraguru Mountains, in Ecuador. In general outline the shape of the flowers differs from that seen in most odontoglots, for the two lower sepals do not spread laterally, but are rather inclined to extend in a parallel fashion under and beyond the lip. When spread out the flowers measure about an inch across. There are no markings on either petals, sepals, or lip. The panicles are about a foot in length, and the small branches carry four or five flowers apiece, so that the whole inflorescence carries some twenty to twenty-four blooms. An illustration of this pretty little orchid, given in the *Bot. Mag.*, t. 7,569, was made from a specimen flowered by Mr. E. H. Woodall, of Scarborough, in April, 1897.

HABENARIA RHODOCHEILA.

This habenaria from southern China is so closely allied to H. militaris, from Cambogia, and a species now so well represented in gardens, that a grower who possesses the latter need not worry much if the former be absent from his collection. Habenaria rhodocheila grows in a similar manner to H. militaris, but seems to vary considerably in the colour of its flowers, from rose-coloured to orange and madder yellow. The species was discovered by Dr. Sampson close to the monastery of Fi-loi-tze, near Canton, in 1864; the specimens were sent to Dr. Hance, F.L.S., then resident at Whampoa, who subsequently described and named it, describing the flowers as rose-coloured. Tubers sent to Kew by Mr. C. Ford, Superintendent of the Hong Kong Botanic Gardens, were received in January, 1895, and, after cultivation in a warm house, they flowered in June, 1897. The flowers produced were, however, of shades of orange and dark yellow or madder, a dozen or so occurring on each spike. The most prominent organ is the labellum, which measures about an inch in length and has a spur about two inches long; the former is three-lobed, the side lobes being larger than the oblong, deeply two-lobed, central segment; the sepals and petals are green. A figure is given of both plant and flowers in the *Bot. Mag.*, t. 7,571.

PAPHIOPEDILUM (CYPRIPEDIUM) VICTORIA-MARIÆ.

The question of referring all the tropical cypripediums to the genus Paphiopedilum proposed in 1886 by Dr. Pfitzer, or to a similar genus with the title of either Paphiopedium or Paphiopodium, has already been referred to in these columns, so that readers will not be frightened by the above headline. Paphiopedilum Victoria-Mariæ is a native of Sumatra, and bears a considerable resemblance to P. Chamberlainianum, though differing from it in colour and slightly in shape. The foliage is about a foot long, one to two inches broad, and leathery; the upper surface is bright green, with dark green mottlings; lower surface clear bluish green. Several flowers are produced on the tall scapes, but seldom more than two are expanded at one time; the dorsal sepal is orbicular, green, striped longitudinally with dull red, and margined with dull white; petals horizontal, two inches in length, narrow, twisted, bright green, with reddish purple margins. There are ciliate margins to all the foregoing segments. The lip is about two inches long, and has a slight waist-like contraction just below the centre of the broad mouth; dull purple, with a green band round the mouth. A robust orchid, introduced by Messrs. Sander and Co., St. Albans. *Bot. Mag.*, t. 7,573.

SIEVEKINGIA REICHENBACHIANA.

A curious and interesting orchid, and one not by any means devoid of beauty, judging from Mr. Macfarlane's drawing reproduced in the *Bot. Mag.*, t. 7,57[illegible]. The species has small, clustered, ovoid pseudo-bulbs, green, with red blotches on the old ones; each is sheathed in a membranous and red speckled coat that disappears with age; each is also surmounted by a single elliptic-lanceolate leaf, thick, stiff, plicate, and with five strong ribs that are most prominent on the dark green lower surface. These leaves are four to five inches long, by about two broad; surface dark green; the petiole is little more than an inch long. The flowers are produced, about six together, in a pendulous corymb, and measure, individually, about an inch and a quarter across the lateral sepals. The latter organs are straw-coloured, ovate, concave, and membraneous; the petals are as long as the sepals, linear, yellow, and margined with long, flexuose, golden hairs. The lip is a wonderful organ, three-lobed, with large rounded side lobes, and a linear and smaller central one; these are all fringed as in the petals; while, in addition, the disk has five short teeth at the base of the lip, and two long ones at the base of the central lobe. The yellow side lobes are spotted and mottled with deep red. The genus Sievekingia is a small one, containing but four species, viz., S. suavis and S. fimbriata from Costa Rica, S. Jenmani from British Guiana, and S. Reichenbachiana from Ecuador. The latter was discovered by Mr. F. C. Lehman, at an elevation of 2,000 to 3,500 feet on the Andes; this was in 1879, and only one specimen was found. In 1890 Mr. Lehman searched his estate in Cauca and found five more specimens, one of which came to Dorking, where, in the collection of Sir Trevor Lawrence, Bart., it recently flowered.

Tender Marigolds.—Although African and French marigolds are not so highly esteemed as florists' flowers that they can have a special society devoted to them, yet they have in all parts of the kingdom, and especially in the north, many thousands of admirers. The Scottish firm of Dobbie and Co. are entitled to great credit for the now superb form found in these flowers, and doubtless that fine form is very widely diffused. Yet one sees sometimes from German or French seed wretched things in gardens—tall, straggling, coarse-growing, and carrying flowers that have not the least merit, or form, or beauty. Such strains are only fit to be burnt. Our home-raised stocks are far superior to these, and if those who want them will pay a little more, they will then find all the difference between good things and rubbish. The finest strains of Africans give noble, [illegible] double flowers, range, yellow, lemon, and other shades of perfect form, and the French striped; are of moderate height, rather spreading than tall, and in [illegible] case of double flowers having these perfect in form and marking for exhibition.—A. D.

CHRYSANTHEMUMS.

Chrysanthemums for 1898.

It is perhaps due to readers of the Gardeners' Magazine that I should defend my selection of chrysanthemums for exhibition, which appeared in the issue of December 18. My critic, on page 6 in the first number for this year, assumes a modesty in his opening paragraph which is quite refreshing, but not at all characteristic of the man, if we may take his price lists, &c., as any criterion. I may say at once that I had not in mind, when penning my offending list, the especial satisfaction of trade growers. I gave those varieties which, from our own experience and my own personal observation over a lengthy round of shows and other collections, appealed to me as the most suitable, and the most likely to prove satisfactory in the hands of exhibitors. I do not presume to say that my list included only the "best," but "what we considered the best." It is well known that, as a member of the Floral Committee of the N.C.S., and from the fact of my securing the most promising novelties each season, or at any rate what we regard as such, in order to enter in the best competitions, the opportunities are good enough to enable me to speak with some weight on this matter of selection, and more especially as I am entirely unbiassed by trade interests. My selection of varieties is based on the grounds of having to supply a large quantity of exhibition-grown flowers for decorative purposes, as well as having to stand the tests of keen competition at the shows; hence, colour is of vital importance, as also good and consistent varieties. Pains are taken to select from the endless choice presented nowadays those only which give us the best and most effective colours in flowers of graceful form, and with some regard also to the habit of the plants; and I am quite satisfied to leave the results in the hands of readers to compare, as they will, with the varieties urged by your correspondent. My selection was offered as a solution of the bewildering difficulties some experience in deciding what not to grow, particularly in limited collections. Each year this becomes more difficult, owing to the large number of comparatively worthless varieties offered with such glowing descriptions. We annually discard some fifty or more Japanese varieties, and Mr. Mease, the well-known grower and prize winner, assured me it was the same with the collection at Leatherhead. This yearly weeding-out must obtain, to admit a fair share of novelties, some of which will turn out improvements, and others prove disappointing; but all the same, the fascination of new things impels us to try a goodly number each year.

I will briefly discuss these varieties set forward in opposition to my own choice. First, Pride of Madford: this, as I have before remarked, does not commend itself as one of the best twenty-four owing to its incurving character, which does not exhibit sufficiently the rich colour of the surface of the florets unless these are artificially turned back. Madame Ad. Moulin has always been consistently good here; the blooms are large and the florets long, of a graceful drooping habit, and white in colour; it will still be grown here. Of the others named in the paragraph Madame Gustave Henry, V. Roger de Chezelles, and Mons. Andre, we discarded two years ago after a season's trial, and, despite the fact that two have received the F.C.C. of the N.S.C., I still maintain they are not worth growing, even in a large collection. Madame Ad. Chatin cannot compare with Western King; Milano is dull in colour, and lacks refinement and grace in form. Mrs. Charles Blick has proved uncertain with us and elsewhere also, judging from the shows during the past two seasons, though it has been shown well occasionally. Pride of Exmouth and Mons. Hoste are of poor colour; washy and undecided mauve tints are not desirable for decorating nor on a show board. Louise is small unless really well grown, hence not in the first fifty varieties. Mdlle. Thérèse Rey we still regard as a first-rate flower, and as it was at the head of the list of Japanese in 1894 surely it is in the best fifty now. Lady Saunders has one of the most exquisitely delicate tints of sulphur yellow in the centre, and as we used it in the back row at the N.C.S. Jubilee Exhibition it does not lack size. Sunflower is a most lovely yellow, and a great favourite with many besides myself. I did not place Sunstone or Mrs. F. A. Bevan in the best twenty-four, because the former, though a meritorious variety, has not the charm in its closely intermingling petals which I look for in a best variety, and the colour, though unique amongst chrysanthemums, is not sufficiently effective. Mrs. Bevan is certainly a charming flower, but is very liable to damping, and hardly large enough for the company of Madame Carnot.

No one save my critic would try to mistake Yellow Madam Carnot as meaning Mrs. W. Mease; and as I recommended the former with Western King, John Neville, Mrs. Bevan, Mrs. Palmer, and Snowdon, amongst others, as novelties for 1897 (page 119 of that year) it would be careless on my part to call them novelties for 1898. It is a hard matter to say what is new nowadays when none are old, and I must crave the indulgence of my readers for mentioning as new, Madame P. Rivoire, which though put in commerce in 1896, is still not mentioned in the 1897 or 1898 catalogues of either Mr. H. J. Jones or Mr. Norman Davis, and has only come into prominence lately, through its being awarded a F.C.C. by the N.C.S. committee. I saw in the past season for the first time some excellent blooms of C. E. Jeffcock, so that it has some claim to be called new. Ella Curtis, though in some degree promising, will, I fear, always come thin and open in the centre of the flower. That was the character of our own flowers, and also of the blooms submitted to the Floral Committee last autumn; it reminded me of the old Boule d'Or somewhat. Mrs. Maling Grant has proved a failure with us, and Elthorne Beauty is not first-rate. Dr. Liebert I have not seen, it is one of Calvat's last year's introduction. George Seward came very poor with us, though the plants were strong and wellgrown, but there were some very good blooms shown by Mr. Jones at the December show, which points to its being a late variety, as also is Julia Scaramanga. Joseph Brooks greatly disappointed me: it has not since been shown up to the form displayed by the blooms which obtained the F.C.C. in November, 1896. Lady Hanham may well be famous for its curiously delicate shade of colour and the exquisite form inherited from its parent Viviand Morel, from which well-known variety it is a sport. Topaze Orientale was twice presented before the Floral Committee last November, but the florets are notched and rough, and the blooms did not find favour with members, nor did it appear likely to develop good incurved blooms, though, of course, it may be that the wrong bud was selected, and another year's growing will prove its worth.

I maintain also that my having selected a large proportion of white and yellow-coloured varieties in no way weakens my selection, for these colours predominate in chrysanthemums, and a stand of twenty-four varieties may contain six or even seven each of white and yellow flowers, providing crimson and other bright colours are used in like proportion. Certainly it is far better to show a good stand half of white and half of yellow forms, than to include such bad types and others as are often shown, like Mrs. Harman Payne, Ethel Addison, and Van den Heede for instance. At the same time, if really good blooms of rich and effective tones of colour can be obtained, they enhance the value of a mixed exhibit by giving as great a variety as possible.

Trent Park Gardens. W. H. Lees.

The Price of New Chrysanthemums.

The remarks of Mr. W. H. Lees on p. 823 of the Gardeners' Magazine of December 25, with respect to the price of G. J. Warren, seem to need some response from me. When I submitted the chrysanthemum in question to the meeting of the N.C.S. Floral Committee in November, 1896, I had but one plant of it, and had decided not to distribute the variety until 1898. However, after a conversation with Mr. W. H. Lees, and as a consequence of it, I decided to distribute G. J. Warren in 1897; Mr. Lees knew what the price would be, and also that I could not accept many orders. He also knew I could not guarantee plants until April. I was able, however, to dispatch the first fifty plants on March 15, 1897, and Mr. Lees having given me the first order he was considered first. I am firmly convinced that Madame Carnot is the best Japanese chrysanthemum, and that G. J. Warren will come next, while these, with the new Mrs. Mease, will make a grand trio. Mr. Lees states that he has not seen a good flower of G. J. Warren; if no good blooms have been shown how was it that the R.H.S. made it an award of merit, and the N.C.S. a first-class certificate? It was also awarded an F.C.C. by the Scottish Horticultural Association. Were none of these nine blooms worthy the honours gained? There was also one bloom of G. J. Warren in my thirty-six novelties at the November show of N.C.S., as good as any Madame Carnot Mr. Lees has staged this last season.

I should also like to ask Mr. Lees whether the plant he complains of was the first he had purchased at 21s., and whether he never previously had one of a new variety that failed to produce an exhibition bloom the first season? The flower of Madame Carnot shown by Mr. Lees at the Aquarium was not to be compared to those shown in 1897, and yet thirty francs, or 25s., had to be paid for each plant. Mr. Lees' remark is an unfortunate one, and tends to damage my reputation, otherwise I should have made no remark. I may add that there will be no cause to complain of having plants of Mrs. Barks, which have been over-propagated.

Earlswood. W. Wells.

EFFECTIVE CLIMBERS.

The wonder is that we do not plant more climbers around or against old trees, or even young ones. For instance, a fine ampelopsis in its beautiful tints of autumn climbing up an old Robinia, hiding the old bare branches, is wonderfully effective. Hardy climbers are, I consider, in their element climbing around and up trees or large bushes, for there they produce effects such as the artist or poet delight in; they do not harm the trees in any way, but produce a beautiful effect. The effect of an ampelopsis twining around an Acer negundo needs to be seen to be realised, and yet how simply these effects are produced. Another sweet and beautiful climber, and an old favourite, is the honeysuckle; both Early Dutch and Late Dutch varieties are very sweet, as are many others, and they are always admired. When planted at the base of trees or shrubs, to make archways in the pleasure grounds in odd out-of-the-way places, even in the shade it matters not, they will grow with perfect freedom everywhere, and when allowed to ramble at will, they are the very objects whose odour always announces their presence. Ivies of various kinds, when planted in suitable places, such as against old walls, up dry poles, or over arches in odd corners, are fine and useful for decoration during the winter; to my mind the ivy is not used nearly as much as it ought to be, and there are some very pretty varieties that will stand smoke and fog; in fact, nothing seems to harm the ivy to any extent.

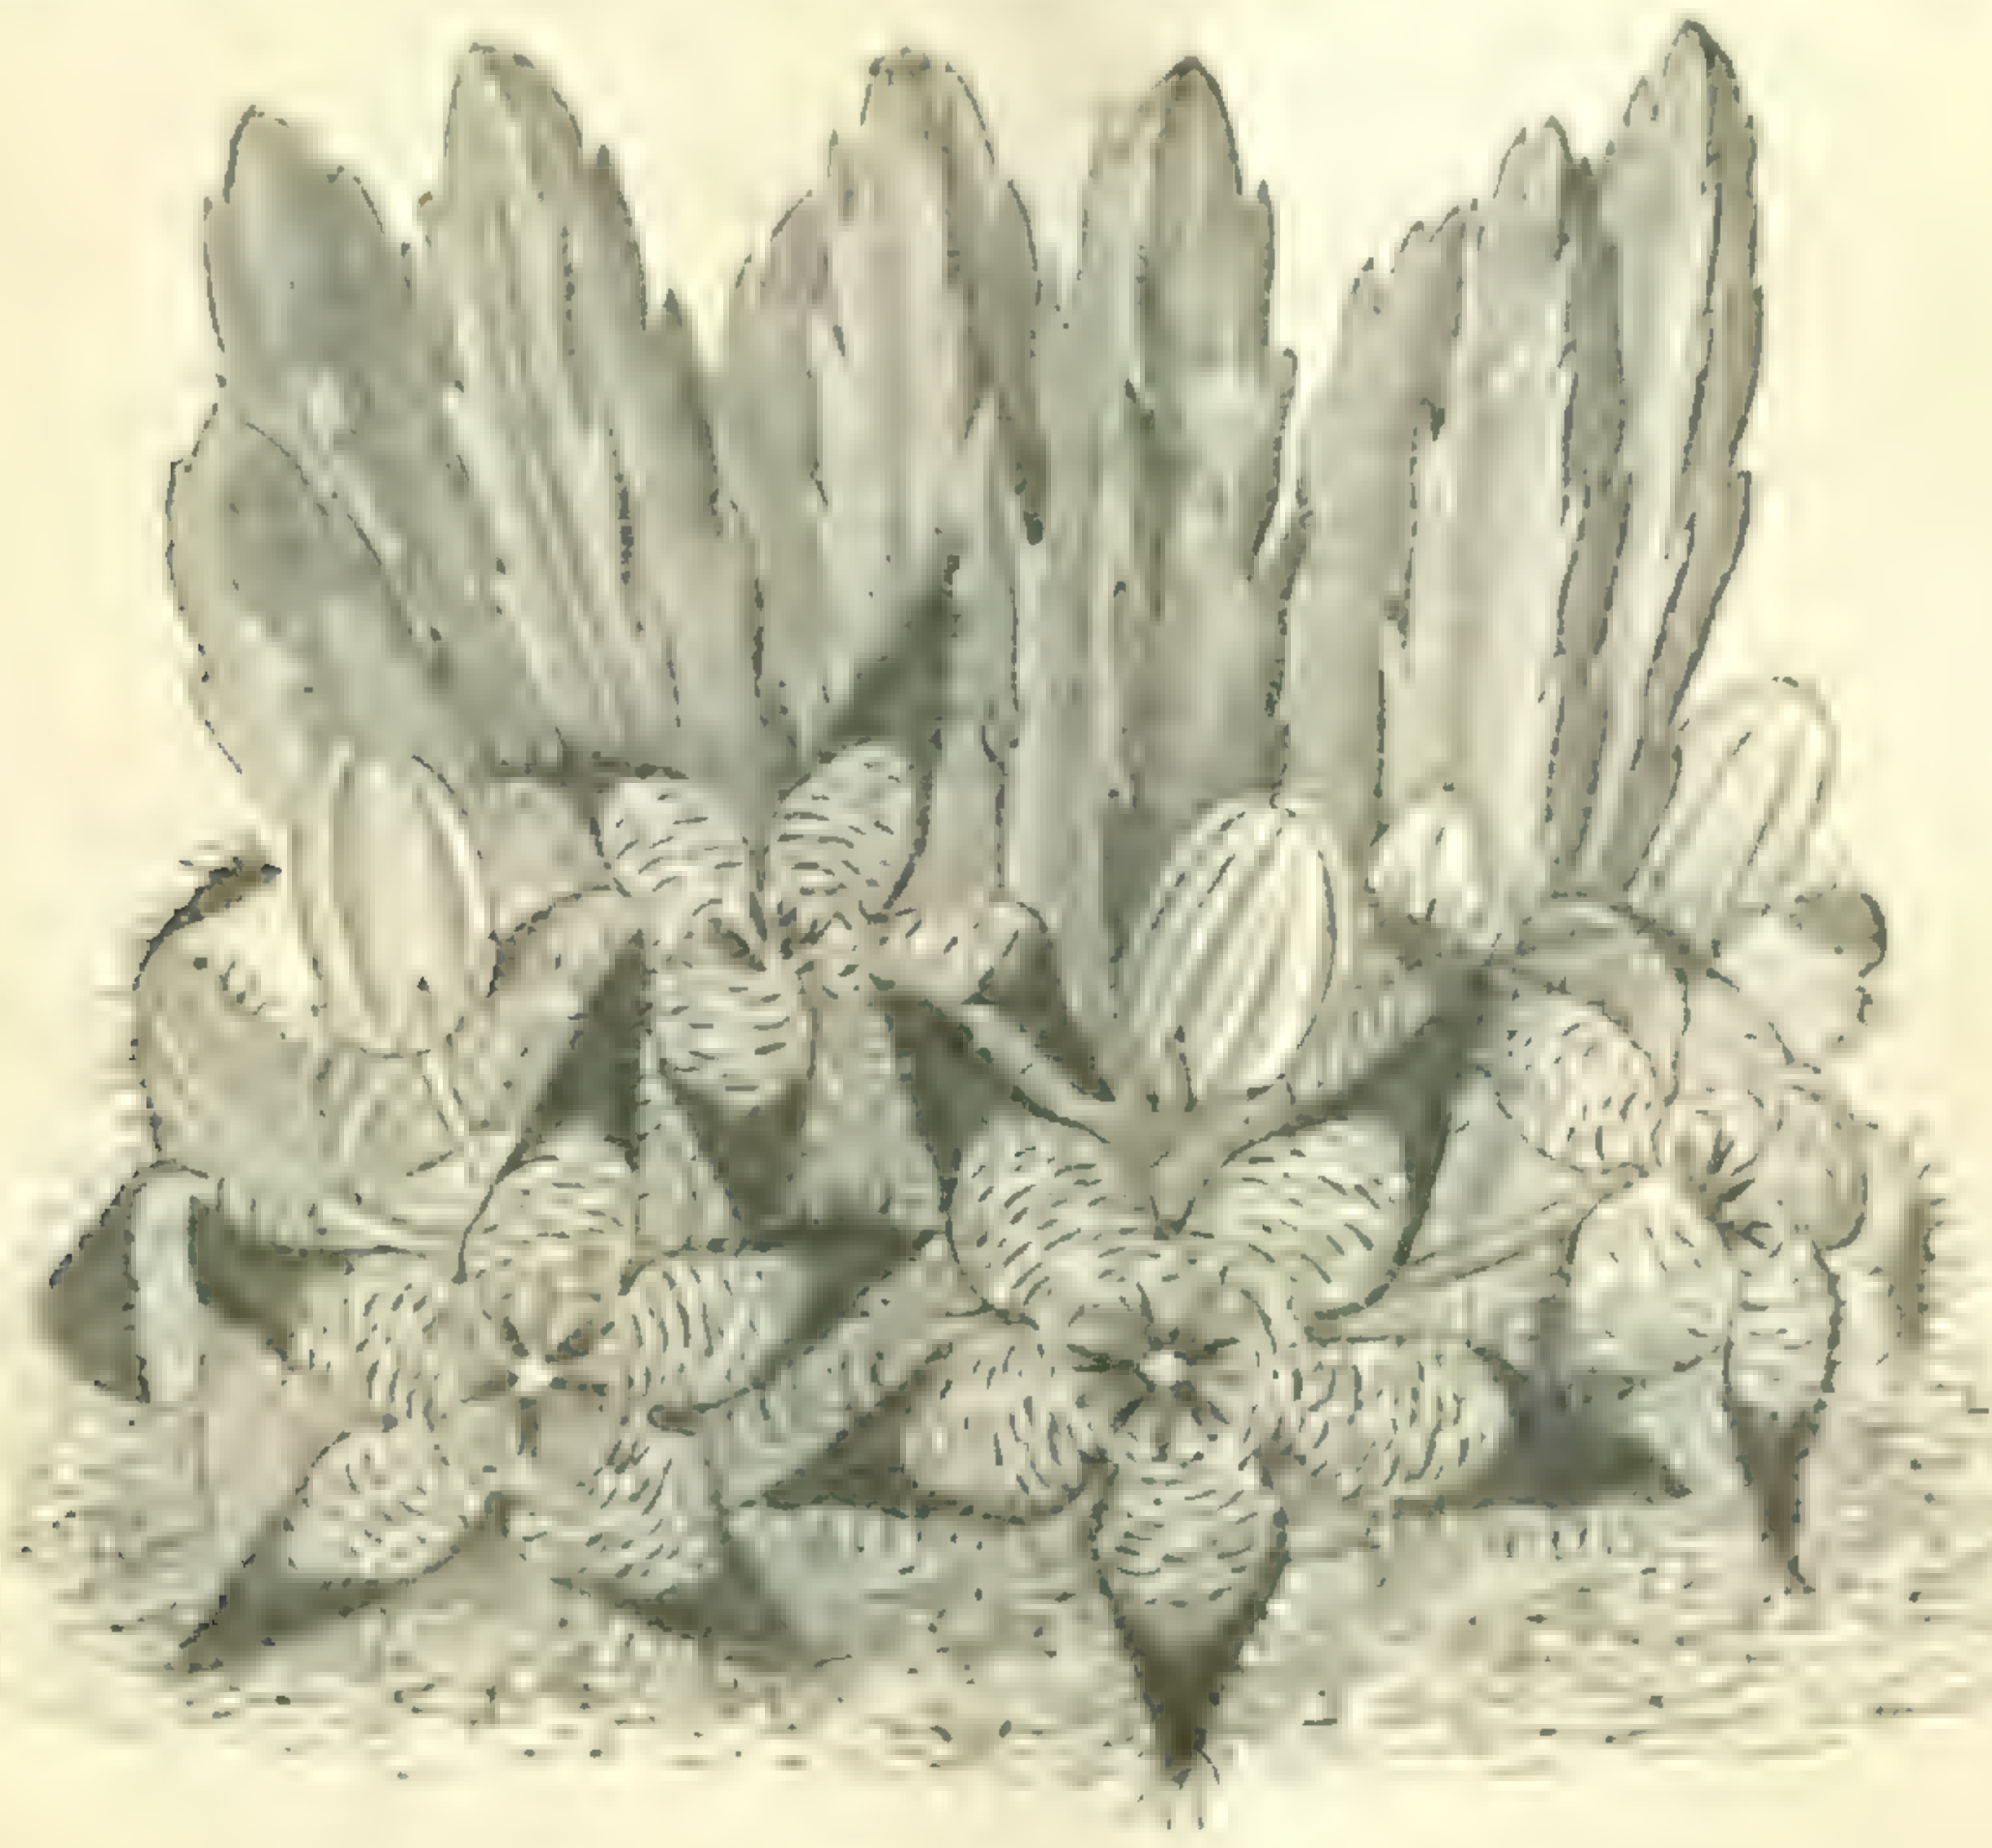
Clematis as climbers are hardly surpassed in their season, and they enliven old walls, trees, arches, and may be even trained up poles with good effect; the great variation of colour in these flowers is charming, and the size of the blooms attracts considerable attention. They are easily grown, and never need a great amount of time spent upon them. A few of these handsome climbers planted in unsightly places will quickly repay the small expense in purchasing and planting. C. Jackmani, C. montana, C. Henryi, C. lanuginosa, C. flammula, and many others of more recent introduction are useful for the purposes mentioned, and their flowering period extends over several months. Another climber most beautiful in its season is the Banksian rose, but this requires a wall, and when a good high wall can be given, it invariably produces good results. When in full bloom there are few more delightful pictures than the Banksian rose, its large clusters of yellow flowers set amongst the shining green foliage being both elegant and effective. This rose is useful for decorating, being without thorns, or, at least, there are very few, and there are many walls in a large establishment that could be much improved by planting some such beautiful climbers, that would be useful as well as ornamental.

Compton Basset. W. A. Cook.

Crown Woods and Forests.—The report for the year ended 31st March, 1897, of the Commissioner in charge of the Crown woods and forests has been issued. The property under the direction of the Commissioner comprises the New Forest, Dean Forest, and the whole Crown property in Wales, County Monmouth, in Scotland, in Ireland, and in the Isles of Man and Alderney. The income derived from the New Forest from sales of forest produce, amounted in the year 1896-7 to £7,355 4s. 11d., and certain service rents, amounting in the same year to £3,099 11s. 8d. The income derived from the Forest of Dean from the sources above mentioned amounted to £5,305 17s 7d., and £1,856 12s. 11d. respectively. During the year there were about 660 acres added to the area inclosed for planting purposes. With a view to introduce in the Forest of Dean and the Highmeadow Woods a more scientific and systematic system of forest cultivation than has hitherto been adopted, the Commission has arranged with an experienced Conservator of Forests in the Indian Forest Service to make a detailed examination of the woods, &c., and furnish a report on them. It is desired not only to improve the prospective yield of the forest, but also to establish such a system of management as may serve those who desire to study forestry in this country with a good practical object lesson, such as at the present time they have to go to France or Germany to find.

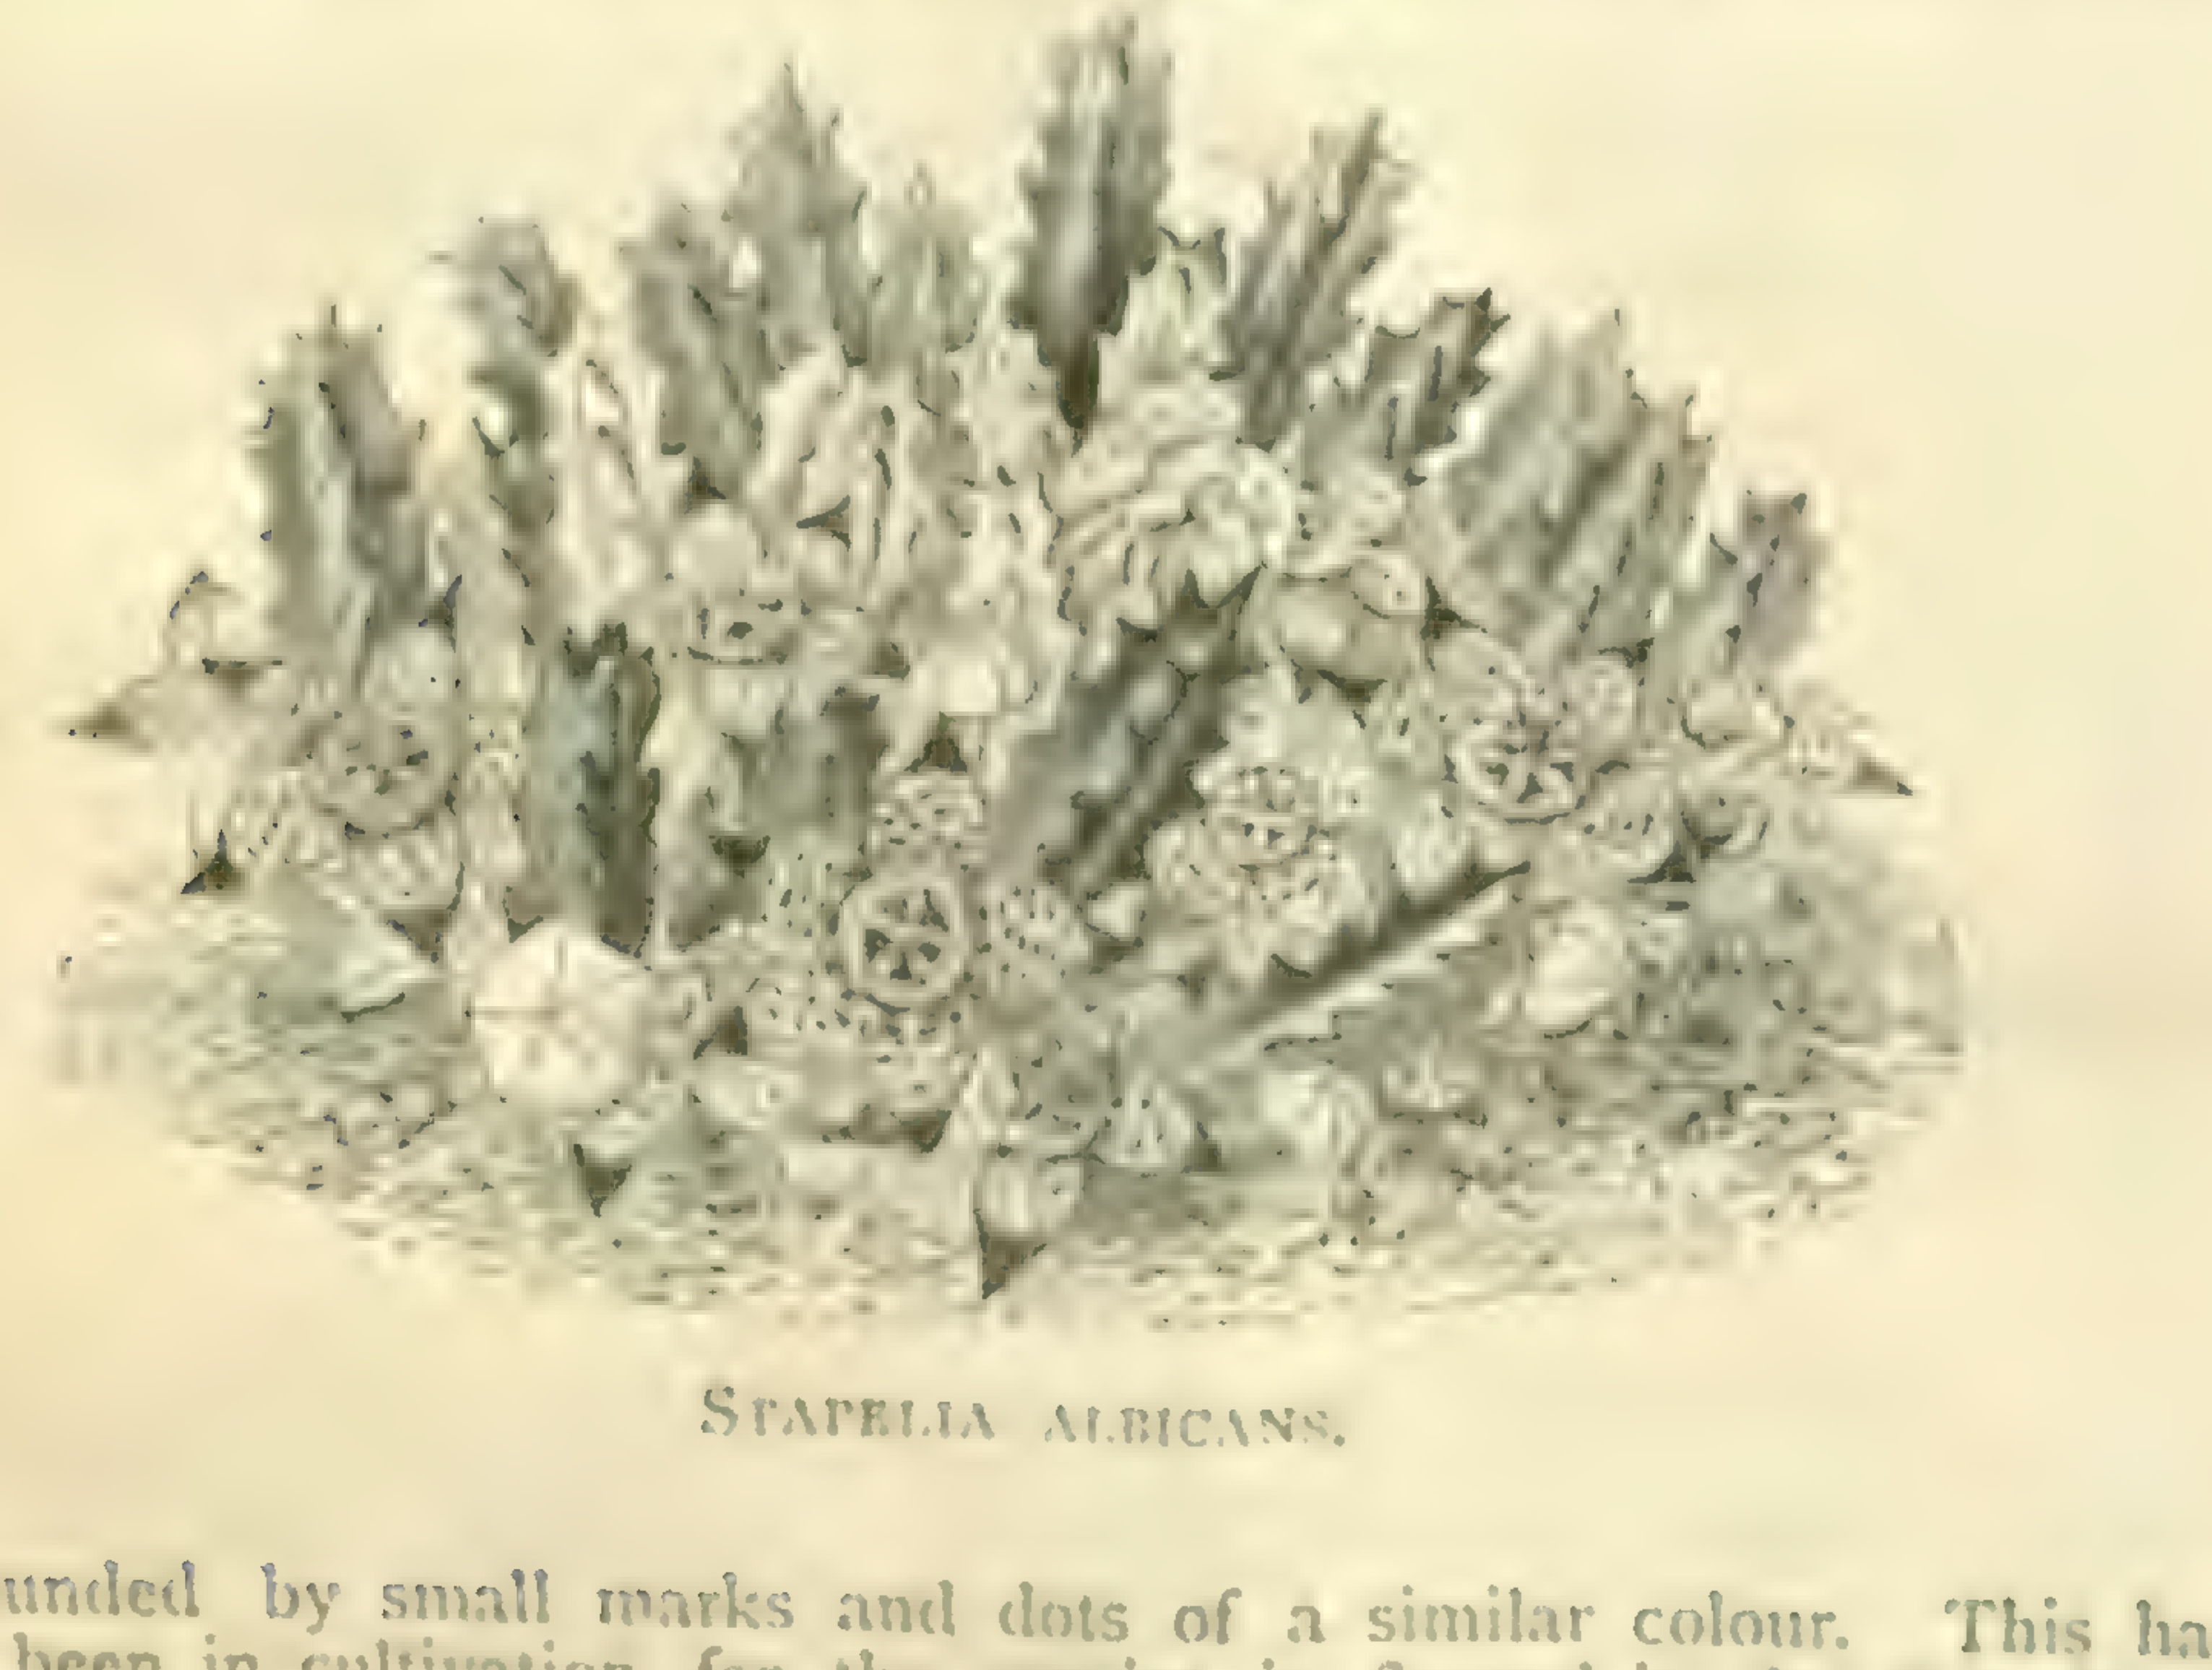
SOME CARRION FLOWERS.

LOVERS of the curious in plants—and who is not attracted by a curiosity?—have always had a strong regard for the succulent stemmed, leafless stapelias; South African plants, producing fairly large, showy flowers that give forth such a fœtid odour as to bring upon themselves the designation of Carrion Flowers. The genus is an extensive one, and includes, among its larger members the interesting Stapelia gigantea, S. Asterias, S. grandiflora, S. Bayfieldi, S. glabriflora, S. normalis, and S. unguipetala. As a rule, the carrion flowers grow best in a warm, dry house, in a light and sunny position. They should be potted in a compost of sandy loam, to which has been added a large proportion of brick or mortar rubbish broken up rather small. In addition to this, the pots must be well drained, or damping will be the result; water is needed in moderate supply during summer and when growth is most vigorous, but scarcely any is necessary during winter. S. gigantea succeeds under conditions of more moisture and heat than would agree with the majority. A shelf on the lightest and warmest side of an intermediate house, especially if the house is kept moderately dry, will be an excellent position on which to place a few specimens of these most interesting subjects. With respect to propagation, most people fail because they are too careful and insert a cutting as soon as it is taken. The result is, that the growth damps at the base, rot sets in, and no new plant is formed. When a cutting is taken from a plant put it on the shelf for a few days, where it will not be moistened in any way, but where the influence of sun and dry air will dry up and heal the cut. When this has happened, and not till then, is it advisable to insert the cutting in any compost.



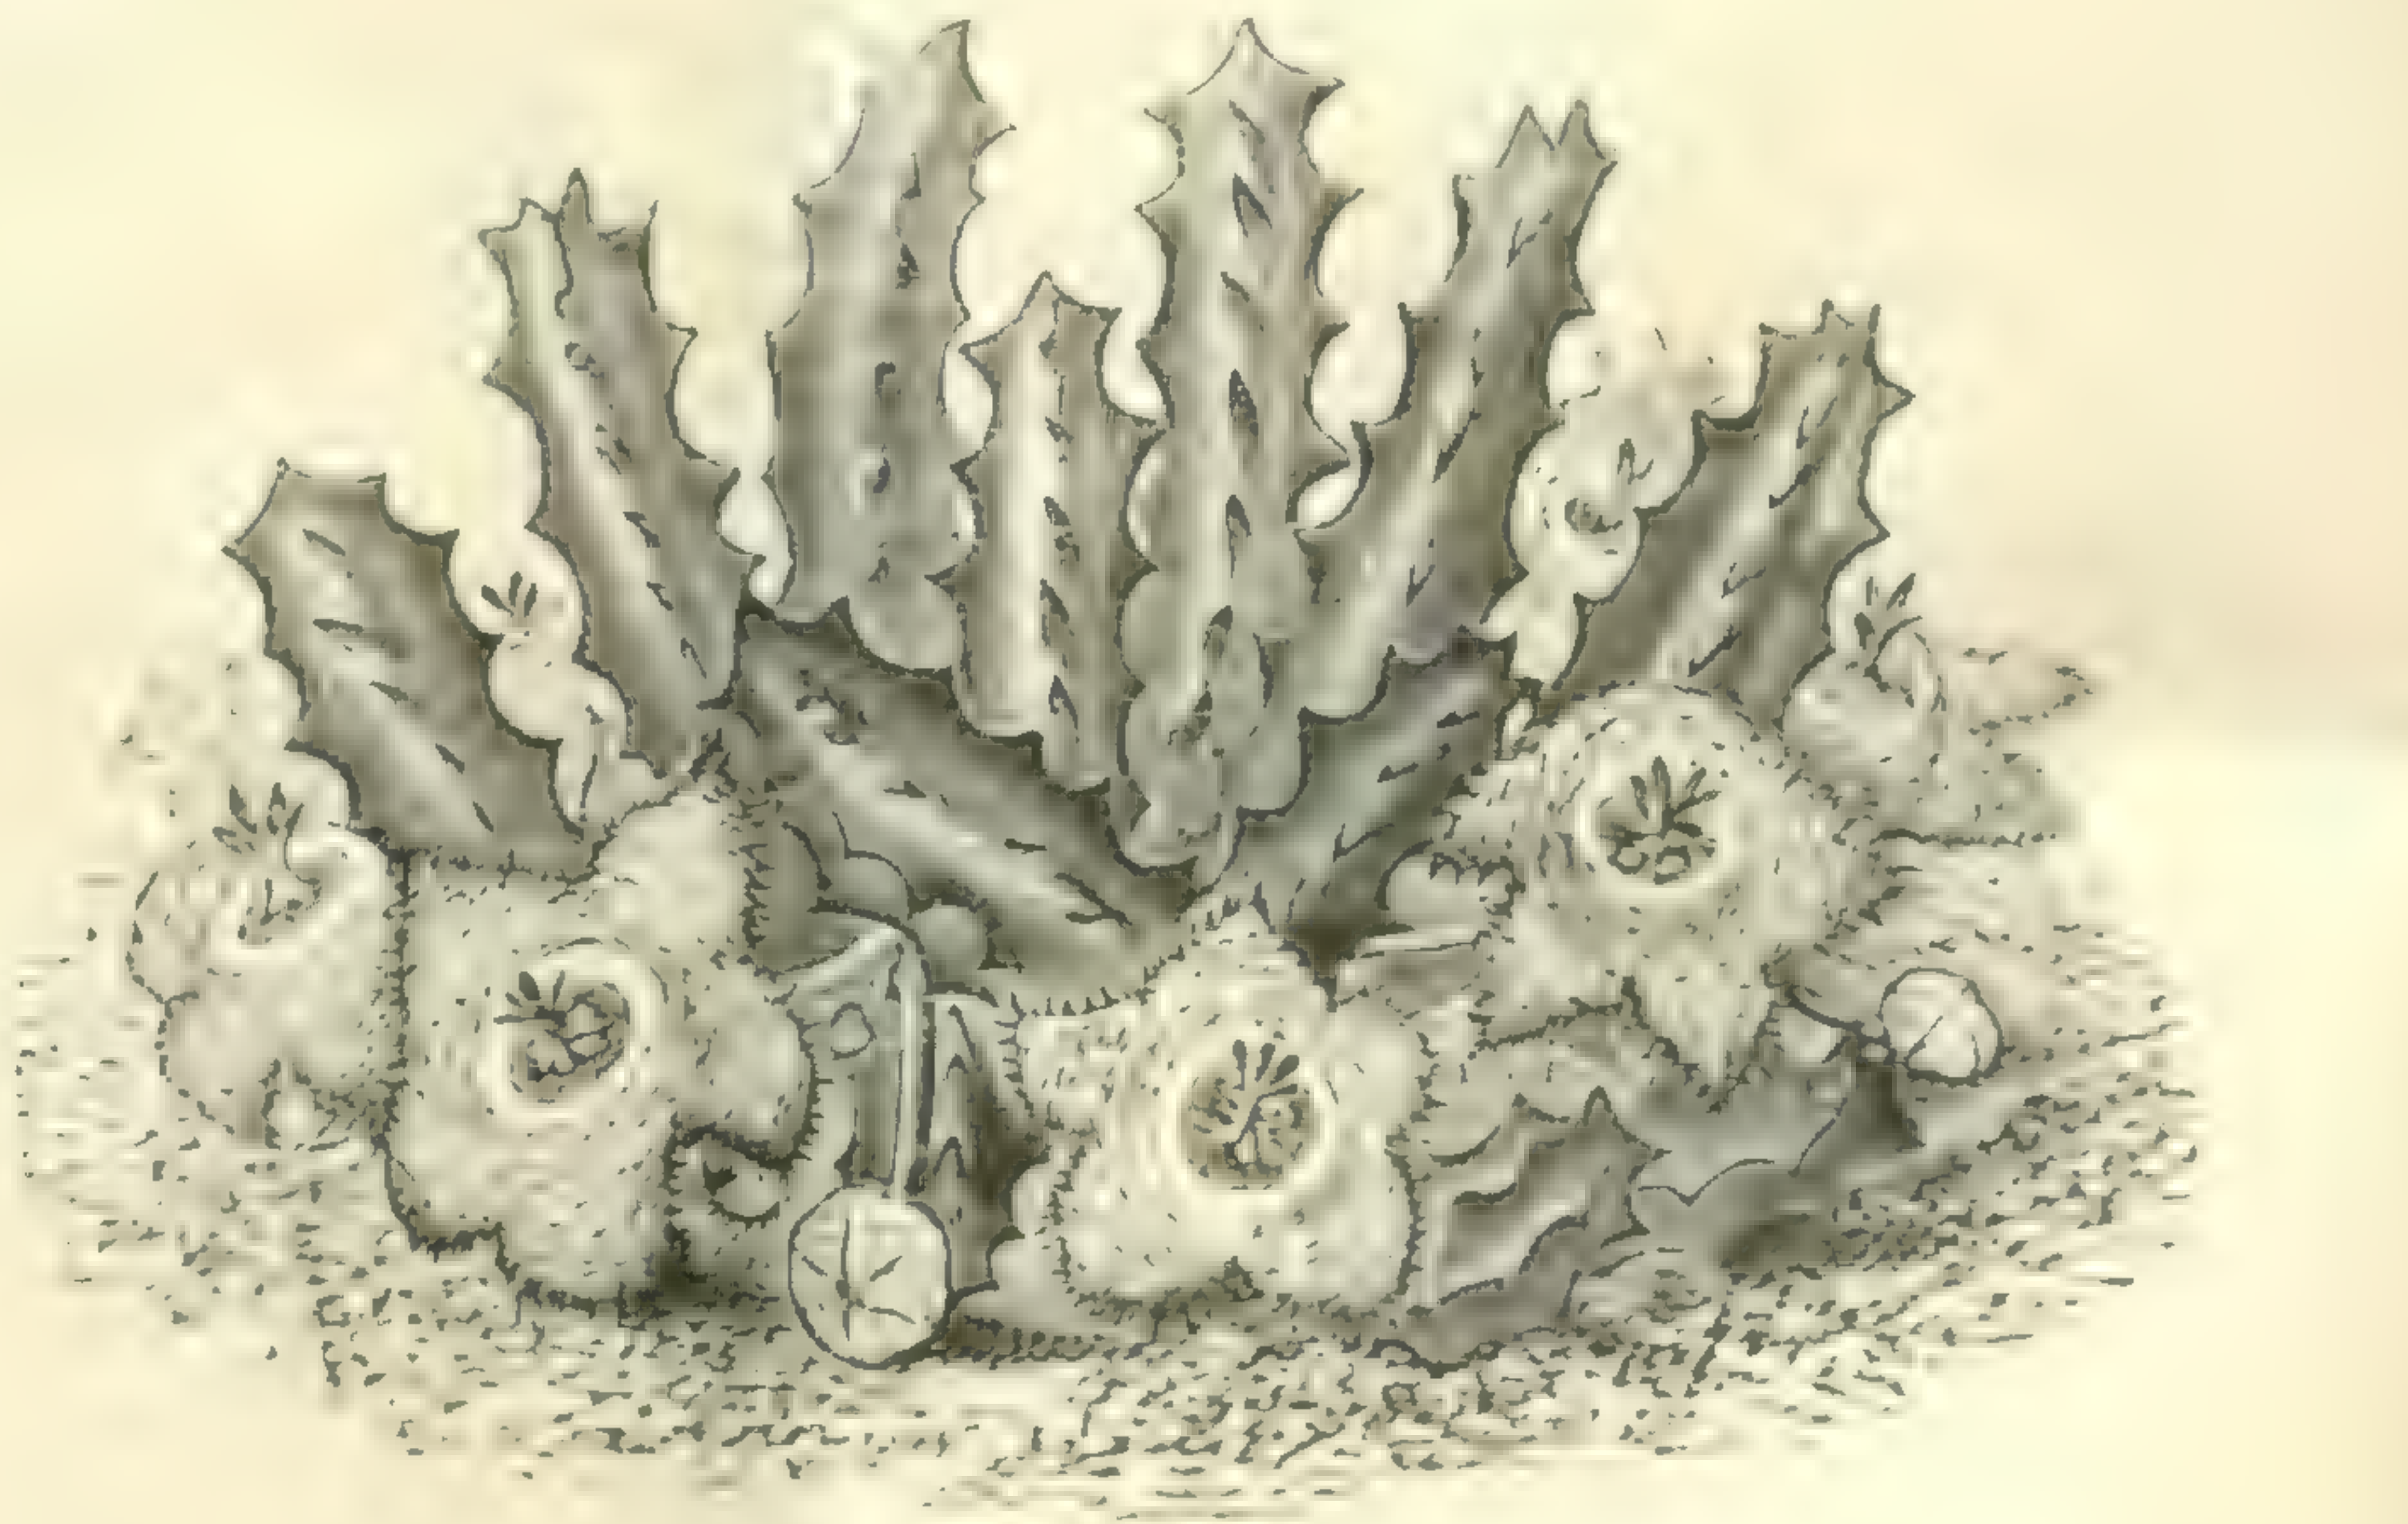
STAPELIA PATULA.

Small growing species are at present most in request by amateurs and others, and the following four combine with that quality a wonderful degree of quaintness in stem and flower, and while the colours of the latter are most attractive. Stapelia revoluta is remarkable for its turned-back segments and for the club-shaped glands that fringe their margins. The colour is deep-red-purple, with a dull yellowish, ten-lobed centre, surrounded by small marks and dots of a similar colour. This has long been in cultivation, for the species is figured in the *Bot. Mag.*, 724, published 1804, from a plant that flowered in a Vauxhall garden. S. albicans is not much known, but it is distinct by reason of the waxy whiteness of its stems and the brown colour of its very starry flowers; it is very free flowering, small and freely branched. S. verrucosa is of peculiar growth, the stems being more or less quadrangular and furnished with distant horizontal teeth of considerable size. Its flowers are of a deep yellow colour, freely spotted with very dark purple; the corona consists of five lower dark purple segments, with five upper and yellow ones. A very showy species with a bluish glaucous hue in the stems. S. patula has very erect growth and the numerous teeth along the four ribs of the stems, all point upwards. The segments of the flowers are slightly turned back at the tips; orange coloured, with a paler centre. marked with red. In this species, as in S. revoluta, the margins of the five radiating segments are fringed.



STAPELIA ALBICANS.

During a period of thirty-three years, that is from 1790 to 1823, no less than twenty species of these remarkable plants were figured in the *Bot. Mag.*, commencing with S. variegata in the first vol., and concluding with Stapelia or Huernia barbata in vol. 50. Many have been figured in later times, but this period seems to have been specially prolific in these and other Cape Plants, as doubtless there were better facilities for discovering such, and succulents and bulbs would travel better in those times of long journeys than would shrubby or soft-wooded plants. Then also the peculiar form of growth and flower revealed by stapelias would commend themselves to plant lovers of seventy-five or a hundred years ago, just as a new orchid does at the present day. The following cultural particulars given with the description of S. variegata give us an insight to the methods then obtaining: "If these plants be kept in a very moderate stove in winter, and in summer be placed in an airy glass case, where they may enjoy much fresh air, but screened from wet and cold, they will thrive and flower very well; for although they will live in the open air in summer, and may be kept through the winter in a good greenhouse; yet these plants will not flower so well as those managed the other way. They must have little water given them. Especially in winter. It is very seldom S. variegata produces seed vessels in this country. Miller observes, in upwards of forty years that he cultivated it, he never saw it produce its pods but three times, and then on such plants only as were plunged into the tan-bed in the stove."

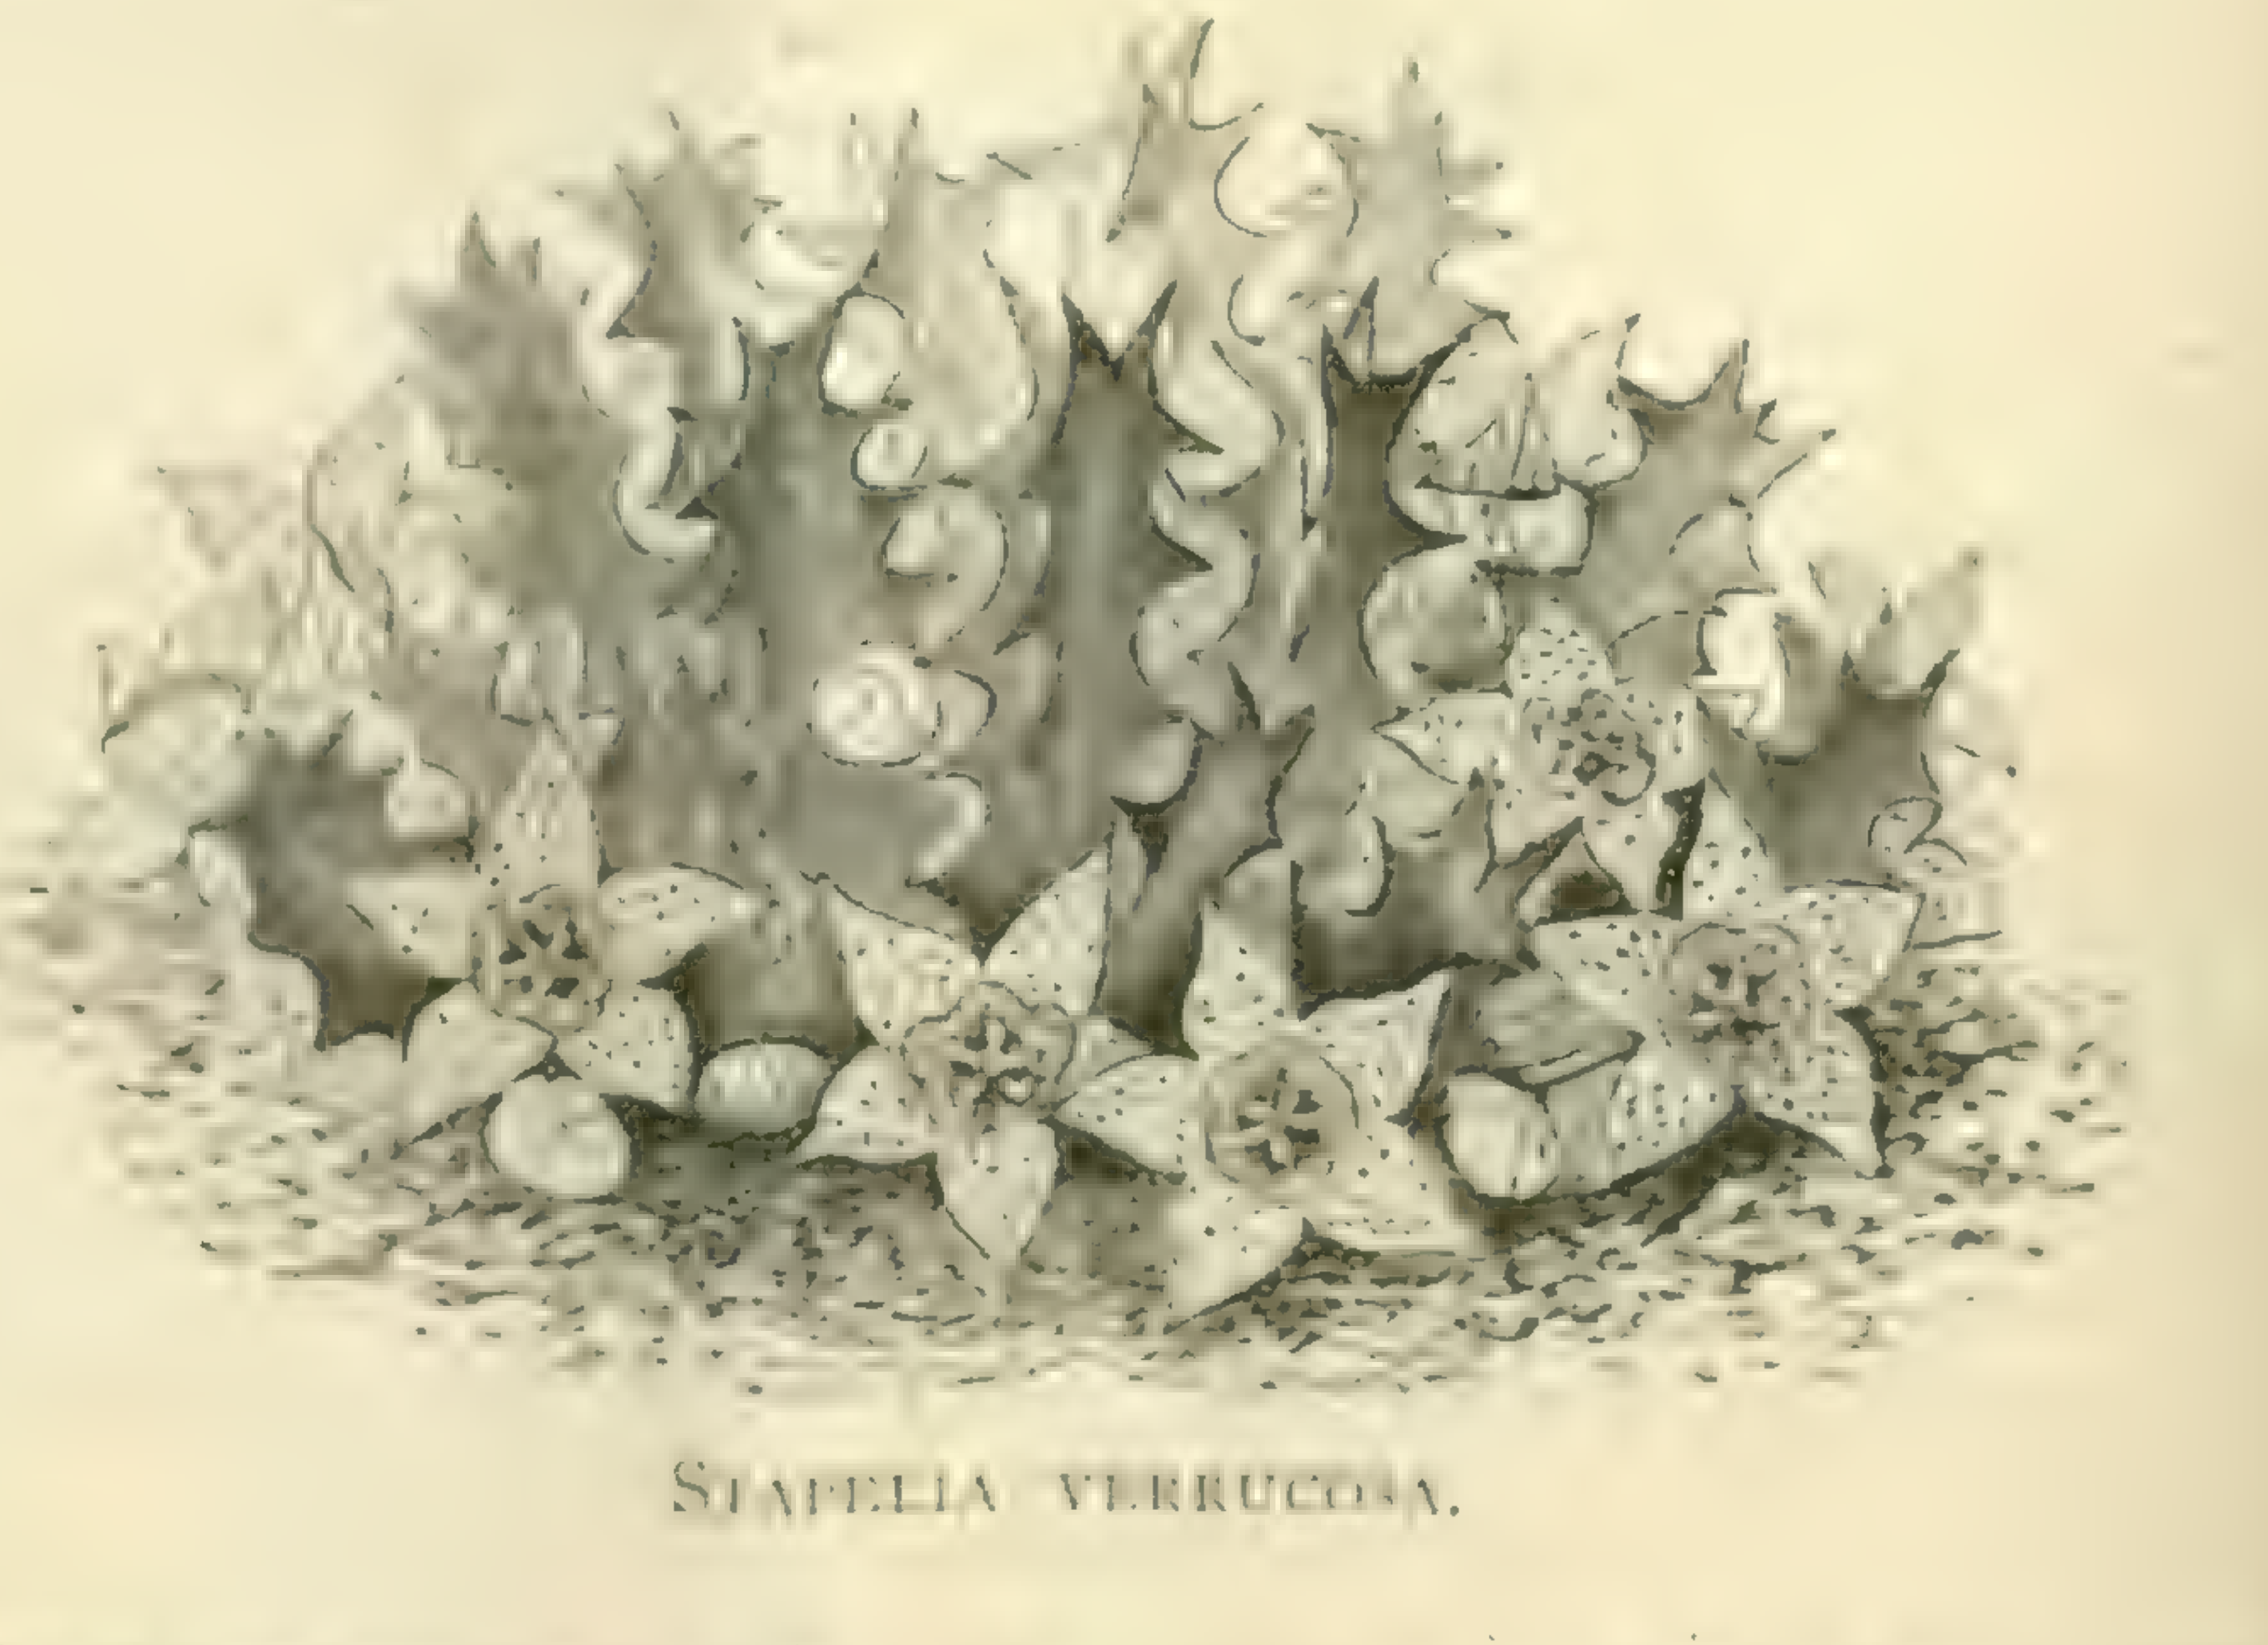


STAPELIA REVOLUTA.

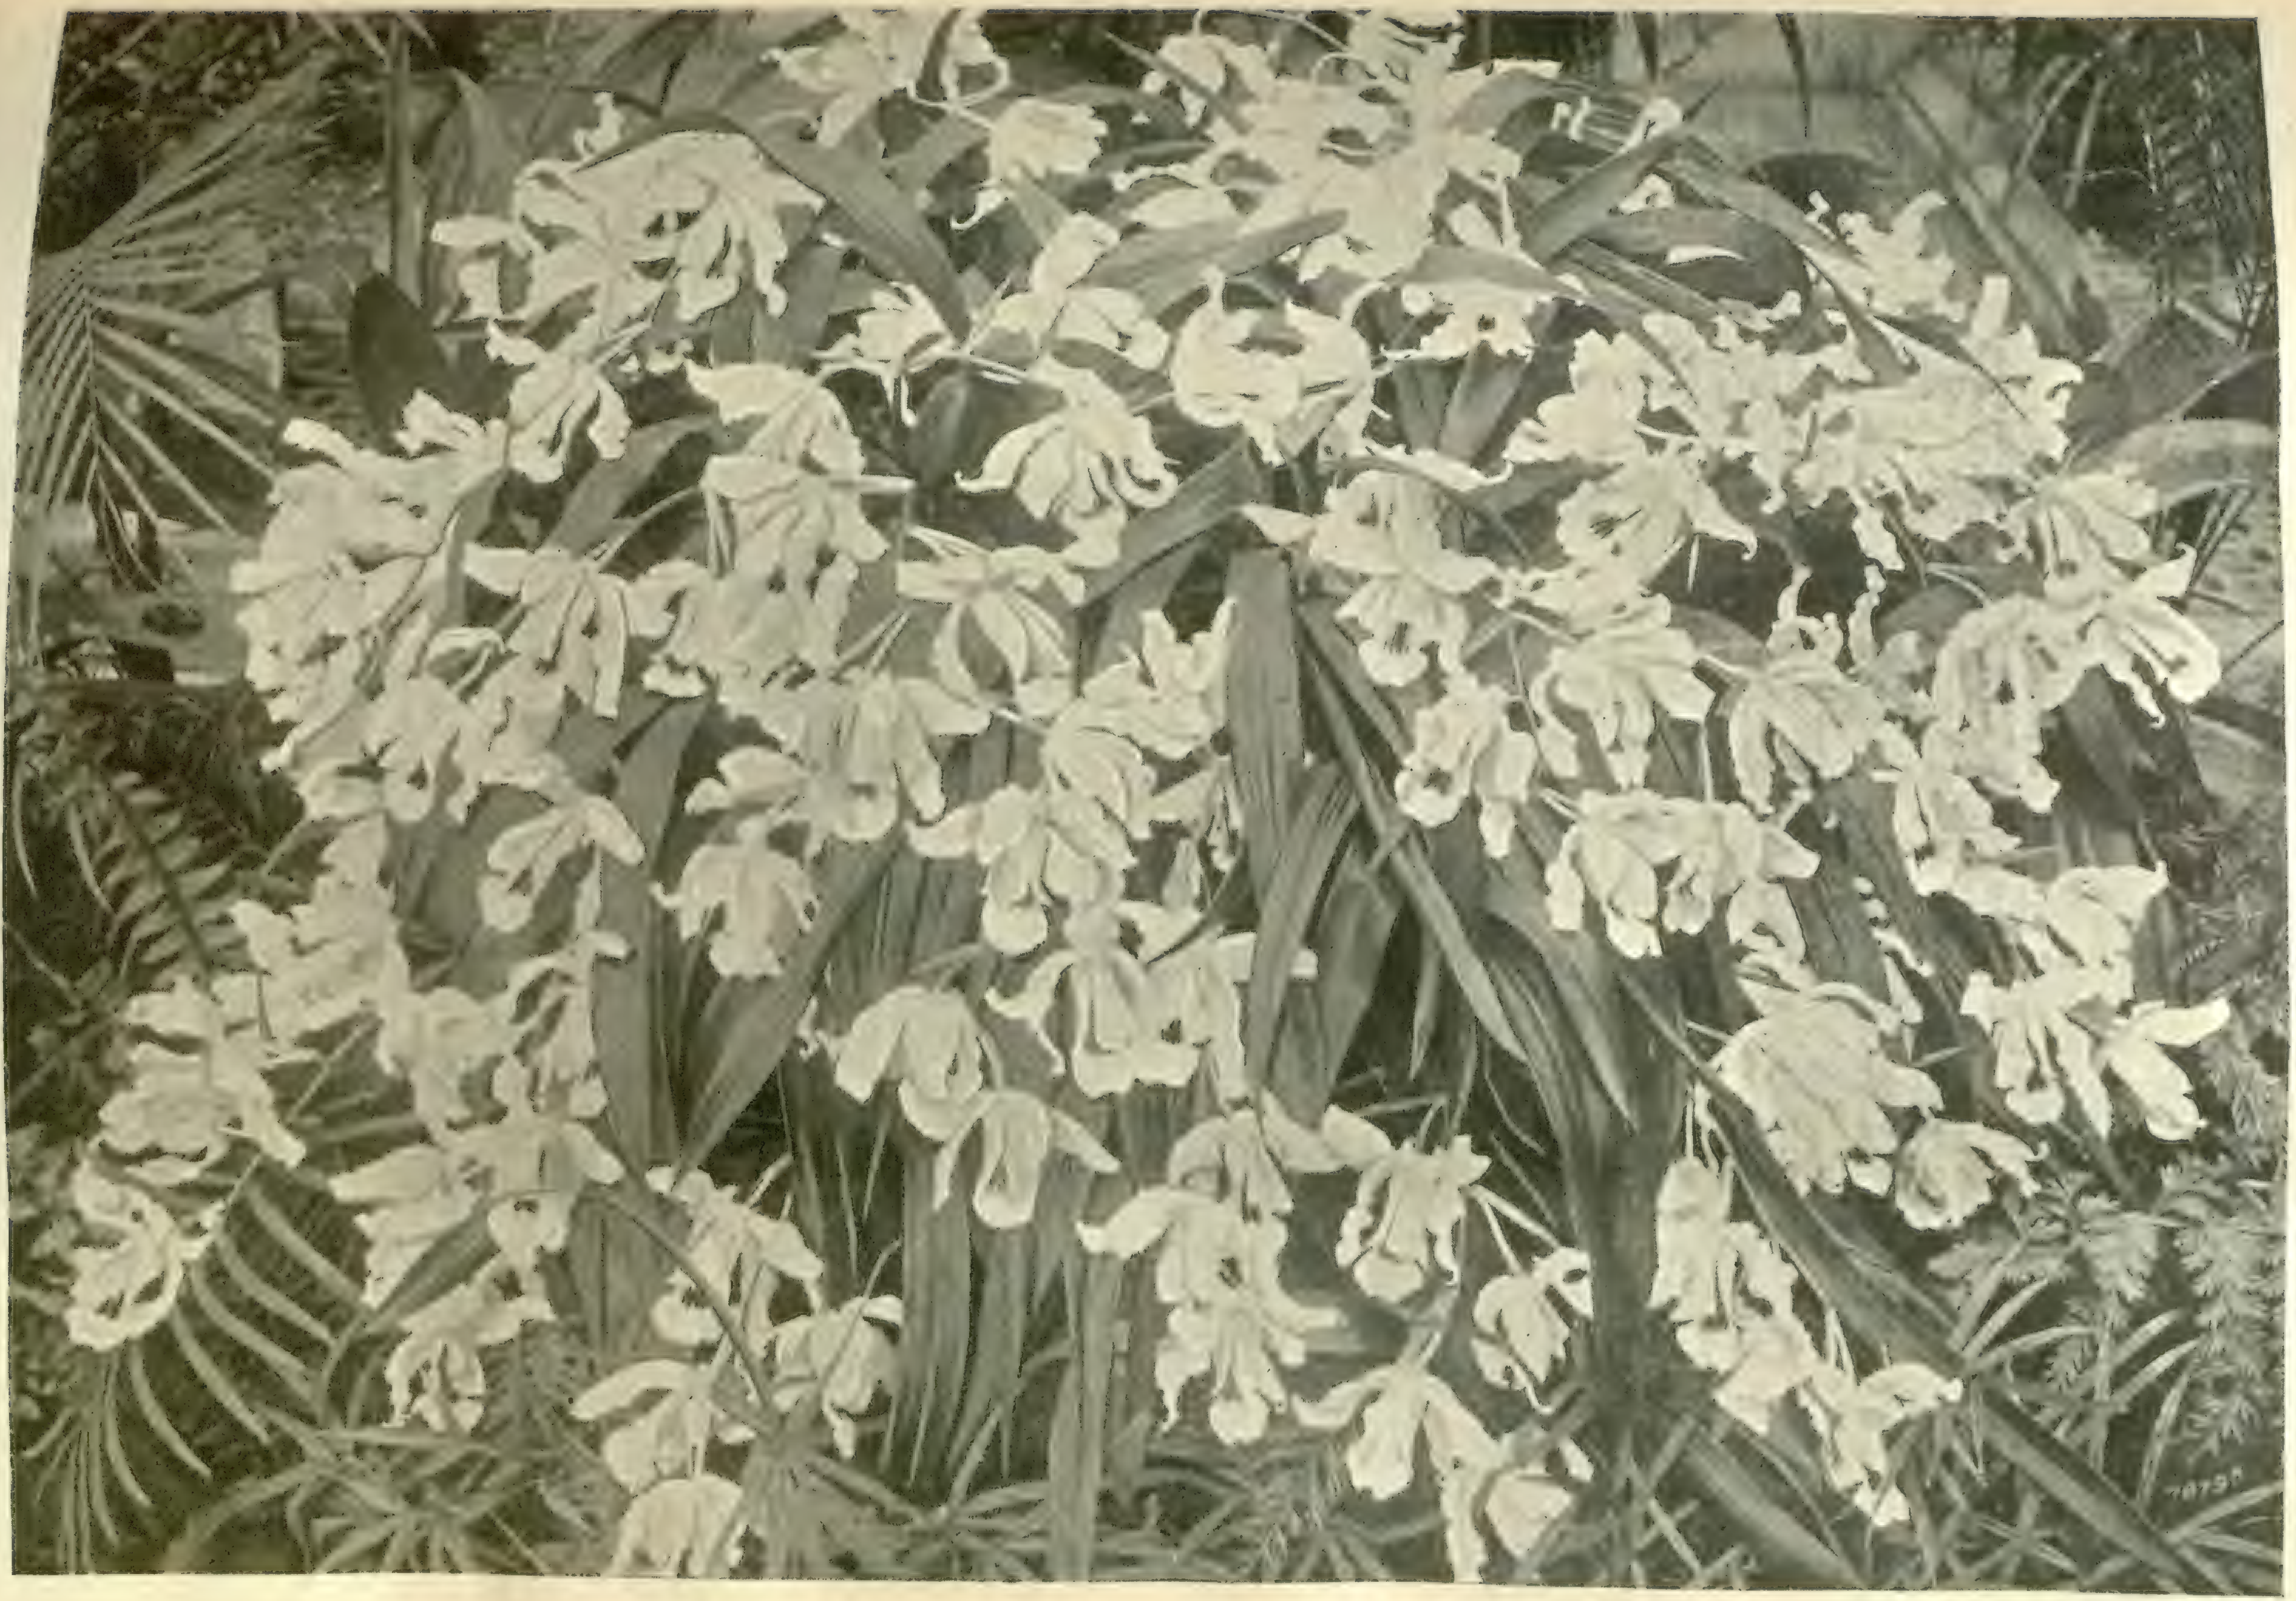
KARL PROSPER, JUN.

CŒLOGYNE CRISTATA AT DEVONHURST.

DEVONHURST, Chiswick, the residence of E. H. Watts, Esq., has a pretty garden attached to it, and one that backs on to the R.H.S. Gardens. Indeed, some part of the Devonhurst gardens were formerly part of the original R.H.S. establishment, as the many fine and somewhat rare trees testify. Successive gardeners at Devonhurst have faithfully upheld its traditions for good gardening, and Mr. James Gibson has even enhanced its reputation. He is very widely known as an excellent vegetable cultivator, and with his exhibits has beaten all comers after travelling as far north as Edinburgh. Orchard house fruits are always a success here, and plants are not forgotten. Among the latter a few species of the most useful orchids are cultivated, and these in due season give results such as any well-known orchid grower might be proud. A good batch of Cœlogyne cristata is cultivated, and most of their time is spent in an intermediate house where ferns, palms, and many subjects required for decorating have to be cultivated. Cooler quarters are given in hot weather. The cœlogynes invariably do well, and flower profusely in early summer, as a glance at the specimen figured in the present issue will show. This example, grown in a comparatively small pan, carried about thirty spikes of fine flowers, and



STAPELIA VERRUCOSA.



SPECIMEN OF CŒLOGYNE CRISTATA GROWN AT DEVONHURST, CHISWICK made an exceedingly pretty picture. Cœlogyne cristata is one of the most beautiful of orchids; it is fine for conservatory decoration, and its white, yellow-throated blossoms are always greatly in request for sprays, bouquets, wreaths, and table decoration. It is a wonderfully accommodating species, and thrives in greenhouse, intermediate house, or stove, provided ample moisture is given, and that it is kept clean. In most gardens it is treated as a cool orchid throughout the year, unless a few plants are put into a warmer house to induce them to flower earlier than the others.

As indicating the adaptability of the species, we may mention that a small piece, consisting of one old bulb and one healthy one with a pair of leaves, was placed in a small sixty pot, in sphagnum and peat, and stood in a hot, moist, and low-roofed stove, some thirteen years ago. It grew and flowered in the second year, and was subsequently put in a pan of moderate size. It increased rapidly, and the growths overhanging the edge of the pan were removed and potted up, until sufficient were obtained to make a good specimen. At present there are three fairly large examples still in the stove, and from which they have never been removed save when the structure has been painted. The variety is a good one, the flowers standing out well on the long racemes. We mention this to show that even in the smallest of gardens, where there is a greenhouse or other glass structure, Cœlogyne cristata may and can be grown.

VINE BORDERS.

WE have recently removed a very old vine border, where the major part of the soil has been for sixty-six years. The soil was from four feet nine inches to five feet nine inches deep, and with very little mixture, in the form of lime rubble and broken bricks, to make the borders porous so that water might pass through freely. When these borders were originally made the first principles of drainage could not have been understood by the makers, and certainly not practised. It is impossible to properly use large quantities of liquid manure on such borders, because in the attempt the water will not pass through, and, supposing there is a dry bottom, the upper surface becomes paste, and sour, whilst the bottom may still be dry, as I have found. No one would be so absurd now as to make such deep borders, therefore it is not necessary to argue about them. In taking out the old soil we came to the division where the border was attended to some ten years ago, and where the depth of soil is about two feet nine inches. The soil here was filled with healthy roots, and moist regularly to the bottom, for the drainage, which was of old bricks, absorbs moisture, and gives it off again to the roots when there is no watering. This was completely full of healthy roots. This is the case always where there is a moderate depth of soil, say under or near three feet in depth, and in all ordinary cases this should not be exceeded; two feet six inches would be much better in low positions, especially when we remember the difficulties there are of obtaining good soil in large quantities.

Shallow, well-drained borders will take a quantity of liquid manure, as it passes away freely, and warm air goes with it, sweetening the whole and raising the temperature; then, also, with ordinary care, there is not the least fear of over-watering. Where water is scarce, perhaps three feet of soil is advisable, as it will not become dry so quickly as a shallower border, a very important point in a dry position and dry summer. I have recently examined such a border we made fourteen years ago, and the drainage is full of roots and perfectly clean, the pieces of brick being covered with healthy vine roots. Lime rubbish is the best material that can be used to preserve the soil in a healthy condition, and it should be used freely near the surface where the use of cow and other liquid manure soon creates a paste, unless the surface is carefully removed annually. I never use organic manure in making a new border as it soon decays, and the borders become sour in a few years. Of lime rubbish about one load to five or six loads of loam should be used with one hundred and fifty to two hundred pounds of coarse bonemeal, a little wood ashes, soot, and some small pieces of crushed brick. If the loam is good yellow stuff such a border will last a long period; black soils do not last so long.

Alnwick Castle Gardens. GEORGE HARRIS.

Artificial Manures.—Seeing that all plants have the same constituents, only more or less combined, and therefore need practically the same food elements, which are chiefly phosphoric acid, potash, and nitrogen, with ample light and air, and atmospheric carbon, I have often wondered in what respect the numerous artificial manures so largely offered in trade can differ. If they are really combinations of plant food, how do they differ? I do not doubt but that properly applied they are all useful plant foods; but seeing that they must be combinations of the three chief artificials—superphosphate, potash, and nitrate—why not call them so, and be content? If any manufacturer asserts that he has in his compound other plant foods or constituents than are those named, I trust he will explain their nature and give their appellations, otherwise there seems to be no reason to think there is difference but in name.—A. D.

The National Chrysanthemum Society. I have heard reports of late in reference to certain proceedings which are said to have been taken by the National Chrysanthemum Society, that, if true, will have a tendency to deprive the society of its national character. The report, as I have heard it, is as follows: The executive of the National Chrysanthemum Society has promised a certain seedsman that if he would offer £30 in prizes for single dishes of vegetables to be competed for at the November show in 1898, they would not accept any prizes for single dishes from any other firm. Also that the society has promised another seedsman that if he will put up a stand of onions and other vegetables at their October show in 1898 they will not allow any other firm to put up a similar exhibit. Now having given the report as received from a most reliable authority, I will withhold anything I may have to say further until I see if the report is contradicted by the officials, and likewise what other members of the seed trade may have to say upon this course of procedure. I think the doors of a national society should be open to all members of any and every branch of horticulture that the officials and members may in their wisdom think well to recognise, all being treated alike.—A LOVER OF EQUALITY.

AQUILEGIAS.

FOR beauty of colour and perfection of form the aquilegia is unrivalled among alpine flowers. The great majority of those natives of the vast mountain ranges of Europe, of Asia, and North America are of inconsiderable size; the aquilegia, on the other hand, is, especially in the instances of A. cærulea and A. chrysantha, a commanding flower, often rising with its luminous blossoms to a height of three feet. Thus, even from a considerable distance, and particularly when assigned a prominent situation, it produces a highly impressive effect. Nothing can be finer, from an artistic point of view, than the varieties to which I have already alluded, when adequately grown. During the season intervening between the last of the auriculas (which usually disappear from our vision in the end of April) and the first appearance of the "regal" rose, there is no flower of the garden with which I am acquainted, not even the tulip, the narcissus, or anemone, which excels the aquilegia, unless, perhaps, in fragrance, an attribute which, however, is not entirely lacking in certain forms, such as A. chrysantha and its hybrids, of this exquisite alpine flower. Not only does the aquilegia make supremely attractive, by the aspect of its delicate and graceful beauty, the early season of summer; but several of its most fascinating forms, including A. canadensis (one of the grandest and most enduring of American species), blooms, with the golden columbine as its fairest contemporary, throughout the greater portion of the month of July; and is especially luxuriant in a cool and shady position where it is not greatly influenced by the somewhat exacting rays of the sun. Being, as I have indicated, entirely alpine in their character, their nature demands for their successful development, such a situation as this. In my own garden, where they appear to be in perfect harmony with their environment, and have manifestly found a congenial soil, I grow them beneath the overhanging boughs of a line of apple trees, and as the blossoms of these and the flowers of the earlier aquilegias come contemporaneously, a varied series of floral pictures is thereby produced, which, as Alexander Smith has sung of a widely different theme, though "fair to the eye," are "still fairer to the memory." Such scenes are especially remembered with pleasure in this season of winter gloom, which is not, however, without its steadfast hopes and abiding consolations, seeing that the snowdrop, the crocus, and the daffodil, with their promise of future and not far-distant loveliness, are already above the ground.

The aquilegia, like the orchid, to which it is frequently compared, not unfavourably, by those cultivators who know the full value of this flower, is found in various, and often widely severed mountain regions of the world; I have not yet heard of it growing in Africa, which is chiefly remarkable for the production of bulbous flowers, especially those of the liliaceous order; but in the other three continents, and prominently in America, its beauty abounds. A. cærulea, one of the hardiest and loveliest of aquilegias, comes to us from the Rocky Mountains. This has been greatly beautified by hybridisation with A. chrysantha, whereby in addition to its effective original colours of blue and white, it has assumed a yellow hue. A. californica, as its name implies, is a native of the Sierra Nevada ranges in California. This is somewhat arduous of culture, and seldom exists for many years, unless under exceptionally favourable conditions of climate and of soil, for which reason I cannot commend it for universal cultivation. It is, however, an aquilegia of great beauty, and should be cultivated for this reason, notwithstanding its unreliability, as it can be treated as an annual, and grown from seed. Its colour is brightest orange, with suggestions of yellow; it is of a peculiarly pendulous habit, and the spurs are very long. Aquilegia chrysantha, so called by reason of its luminous golden-yellow complexion, which easily distinguishes it from all other North American kinds, also belongs to Californian regions. Of all existing forms this is perhaps the most valuable; what Perle des Jardins is among roses adapted for garden cultivation this uniquely-coloured species is among aquilegias; but it is infinitely hardier in character, and opens with greater facility than the somewhat capricious rose to which I have referred. No aquilegia within the range of my acquaintance is so enduring as this; in this respect it is truly remarkable. I have vigorous plants in my garden, sending up in June and July great masses of flowers to a height of three feet, which have, with only one change of position, lasted for ten years. Next to it in value and, with the exception of its colouring, which is a combination of dark orange, scarlet, and yellow, partaking of several of its best characteristics, though it does not grow to an equal height—is Aquilegia canadensis, which, though it may have been originally a native of Canada, was certainly introduced into this country from Virginia.

Aquilegia glandulosa, which is a plant of peculiarly tufted habit, from the Altai Mountains in Siberia, requires for its adequate cultivation in the garden a deep, sandy, and well-drained soil. Even under the most favourable conditions it is not greatly to be relied upon; seldom has it lasted with me much longer than a year; but it is assuredly more easily grown than A. Stuarti, which, partaking of the same colours, viz., white and blue, and inheriting from this beautiful species, crossed with A. Witmaniana, its finest attributes, would be, if only perfectly reliable (which I am certain it is not), an invaluable acquisition. Its famous raiser, Dr. Stuart, can grow it in Berwickshire with considerable success, for in that region it seems to find a comparatively congenial soil; but even there it refuses to be treated as a biennial, as it is manifestly lacking in endurance and strength. There are many other aquilegias, such as A. Skinneri, of brilliant complexion, and Aquilegia alpina superba, which by reason of their highly decorative capabilities, are well worth cultivating wherever they can be induced to flower with facility. Aquilegia alba, which I like much better than its double form, A alba flore pleno, while distinctive in colour, is much more hardy in character than these. But greatly more attractive than any of the latter, and rivalling, if not absolutely surpassing in brilliancy the nobly-endowed North-western American forms, are the exquisite hybrids raised and introduced by Messrs. Veitch, which have, in addition to their lustrous beauty, a supreme qualification for most gardens—they are not liable to decay.

Kirkmaiden. DAVID R. WILLIAMSON.

Work for the Week.

WARM ORCHIDS.

We have now fairly entered upon another year, and it will be a good plan to have a general look round and see what progress we have made in the one that has just passed. Most likely, when 1897 came in, we made up our minds that everything we took in hand was to be a success. What are the results of our efforts? I am afraid in some cases it has been a failure. Fortunately, even a failure may teach us something. Without a doubt, people know more of orchids now than ever they did. When amateurs begin to grow them, the first thing they do is to look out for something cheap to experiment on; very often they go to a sale and purchase a lot of worn-out stuff, and think what a wonderful bargain they have made, and boast about getting them so cheap, whereas they find them very dear in the end. Far better throw them on the fire, and start with good healthy plants, than nurse old exhausted ones year after year, these producing perhaps a single puny little flower that causes vexation and very likely a giving up of orchid growing. We must make up our minds for failures more or less; we cannot expect everything to do well. If any plant thrives in a certain position let it remain there. A deal is said at times about feeding orchids; this is a very unsafe business unless we are well experienced; a little can be done in a proper manner, but the plants must be studied well and fed by degrees. Orchid collections at the present date consist of a comparatively few genera and species; of course there are exceptions, and yet a great many very pretty orchids are comparatively unknown and considered to be of no value, save to the orchid lover; it is a great pity that such have been so little cultivated, for they all have their good qualities. Be they large or small, they flower at different periods, and there is always something about them to interest you. Vandas once upon a time held a high position in collections, but now only a few species are grown. V. cærulea and V. Kimballiana have of late years come to the front, but this is chiefly owing to the quantity that has been imported. We see them grown in various ways; some are grown in the hottest house, others grow them intermediate, and many advise the odontoglossum house; the latter brings out the colour well, but in their growing season these plants naturally require to be removed to a warmer temperature.

The weather again is warmer, so fire heat can be reduced so long as the proper temperatures are kept up. A good damping in the morning is quite sufficient, damping well about the pipes; do not water the plants unless this is necessary. Odontoglossum vexillarium is now making growth, and must be well attended to, Cattleyas will require water about once a week. C. Trianæ, in variety, has now its spikes pretty well up in the sheaths, and must be kept at the warm end of the cattleya house; more water may also be given. Where spikes of C. Percivaliana have come through the sheath the specimens must be treated in the same way. A good plan is to place them along with Lælia purpurata, Cattleya labiata, C. autumnalis, and C. aurea all together at the warmest end, but do not give these water unless necessary, as they are liable to rot at the base of the leaf. If rot takes place, take a sharp knife and give the bulb a clean cut across and cover the cut with dried lime or flower of sulphur, and after this keep the plant dry at the root. You may even allow Cattleya aurea to shrivel somewhat without harm, for the pseudo-bulbs soon plump up when the time comes, that is, if shrivelling is not too severe; this species is best grown near the glass, about six inches from it, in baskets hanging just over the edge of the stage, for in this position they have the benefit of a little more heat as it rises from underneath. Perhaps an odd plant may be sending forth a cluster of young roots; if so, and rebasketing or placing in new pans is required, you may do this with safety, taking care not to injure the roots; careful watering is very important afterwards, so do not study about the sphagnum suffering, as it is an easy matter to add a little when the growing season commences The same treatment is required by Cattleya gigas. I have often seen this begin to grow a second time after flowering, and, in my opinion, they are better pushed on again to make up later in the year, for if well ripened up we may expect them to flower. Some are too anxious for them to rest, and so punish them to prevent growth.

If any dendrobiums of the Ainsworthi section are commencing to grow it is a good plan to remove them to slightly warmer quarters. I do not mean to place them in their growing quarters, but to bring them on by degrees, say in five degrees more heat; this will also give the flower spikes a good chance of developing, and will enable you to get a second growth after the first growth has made up, or you will get a good long stout bulb by the end of the season. Greenfly may be troubling orchids just now, so give each house a fumigating with X-L-all, or anything in this way; if neglected these spoil the flowers, besides being unsightly. Keep on with the sponging and cleaning, and let all the walls be well washed with lime. Attend to ventilation when necessary, for plants, like ourselves, enjoy the fresh air. Temperatures: Dendrobium house (resting), 55 degrees; cattleya house, about 58 degrees; cypripedium house, hot, 65 degrees; ditto, cooler, 55 degrees.—Thomas Stafford, *Tyntesfield Gardens.*

GREENHOUSE AND CONSERVATORY.

To maintain a bright appearance in the conservatory most of the plants used will be the result of forcing, with the exception of camellias, and it is surprising the quantity of water these plants require when in perfect health, especiarly when they are developing their bloom. Large plants growing in the borders of the conservatory, either as bushes or trained to the back wall, should have a thorough soaking at least once a fortnight, but syringing overhead must be dispensed with. To avoid the moisture in the atmosphere settling on the flowering plants a gentle warmth should be kept in the pipes at all times, and whenever possible ventilation should be given at the highest point of the house to allow humidity to escape. Useful and welcome as the chrysanthemum may be for decoration before Christmas, it is not held in much favour here, at least, after that date, and it is certainly a decided change to have the spring flowers to succeed them. Many of the poinsettias will have passed their best, but they require careful management before they are laid to rest. It is a mistake to dry them off quickly, as this causes them to shrivel, and the "eyes," instead of breaking strong when required, only make feeble growth, and puny cuttings result. They should be stored in a warm dry corner where they receive plenty of light, and water at the roots is gradually reduced so that the foliage changes and falls naturally. I stand them under the stage, where they receive the drip from other plants; or in a low temperature is a sure way of causing them to damp and perish. Where a difficulty is found in keeping up a good display of bloom just now, I would recommend the stages to be washed down, and ferns of different kinds arranged thinly to form a base. What flowering plants are available can then be dotted among these, where they will form a more pleasing feature than a number of plants which have lost their freshness. A few foliage plants from the stove which have lost their lower leaves through being used in dwelling rooms will also prove useful for a few weeks, their bright tops giving colour and brightness for the time being.

The greenhouse of the present day is very different to what it was formerly. In well-regulated gardens, good collections of plants were not only grown in them, but were seldom removed either for decorating the rooms or conservatory, but were treated as objects of interest to be only seen in the house allotted them. A house of this description is now generally used for the growing of various things most suited to the requirements of furnishing, and generally find their way to the rubbish heap when they have served their purpose. This keeps the grower always on the alert, and sowing or propagating is going on continually. In this department at the present time late batches of primulas, both single and double, will require a regular temperature of about 55 degrees, varying, of course, during the day with the sun's power. Late sown plants, still occupying four-inch pots, would make a valuable early batch for next season, if the buds were pinched out, and the plants potted on later. Failing this, a pinch of seed may be sown at any time now if large plants, full of bloom, are to be expected next November. Primula seed does not always germinate freely, and many weeks sometimes elapse before growth commences. When the seed is not sown until March, and the above happens, much time is lost which cannot be made up, as the plants resent heat or coddling during the summer months. A brisk heat with plenty of moisture, shaded from sun, with a sandy seed bed, are points which must be observed at sowing time, though the plants revel in a cold north frame; later on a shelf in the stove near the glass is the best position for them until they are large enough to handle. Cyclamen sown last August must not be allowed to starve in thumb pots, but be shifted on as growth increases. If young plants once receive a check either for want of root room or through dryness, the bulbs harden, and it is some time before they can be induced to swell away again. Checks such as these are generally followed by an attack of thrips, the worst enemy these plants are subject to, and it requires a deal of attention to be rid of them. Older plants throwing up bloom should have weak liquid manure occasionally, which will give size and substance to the flowers. Avoid moisture collecting in the crowns, especially in the form of drip from the roof, or the buds will drop off.—R. Parker, *Goodwood Gardens.*

THE FLOWER GARDEN.

With the lengthening of the days work in this department will soon become plentiful. The most trying part of the season for the preservation of summer bedding plants will now have passed, damp and foggy weather requiring more care to guard against loss than even spells of that which is clear and frosty. Acting on the ever-needful principle in gardening, of looking forward, it will now be advisable to examine the stock of bedding pelargoniums, where these are used in quantity especially, and make note of losses or deficiencies that may have occurred otherwise, with a view to working up the numbers necessary to carry out the proposed plans for the coming season. It may be that plants in store pots have, if kept in a warm greenhouse, made growths of a sufficient length that the points may be taken off and used as cuttings forthwith. These should be inserted either in pots or small boxes of light soil, and stood in any warm position in vineries or peach houses recently started, and if over or near the pipes or flues the quicker will root action take place, while the danger from damping off will be reduced to a minimum. Where the stock is requiring considerable addition the stove plants should be potted off singly into sixties and be placed in extra heat until re-established and growths are made that can be eventually used as cuttings. Fuchsias have very generally taken a more important place in the flower garden in the past few years, and their use for this purpose deserves encouragement, for they are free from that stiffness that characterises some other subjects, and for mixed bedding arrangements their culture should not be overlooked. Old plants that were potted up from the beds in the autumn may now be pruned into three or four eyes of last year's growth. If it is desirable to obtain cuttings from these they should be placed in a house with a minimum temperature of 50 to 55 degrees, rising five or ten degrees higher at midday, and the plants be syringed over occasionally. Should propagation not be necessary, these old plants had best remain in a cool house or where frost is just excluded, and be allowed to break naturally. In this way short, sturdy growths will be made later, but all in good time for bedding purposes. Where autumn propagation was carried out the rooted cuttings should ere this be in condition for potting off into single pots, either large or small sixties, according to the strength of the plants, using a light, sandy soil with a free admixture of leaf-mould or jadoo fibre. If strong plants are required by bedding out time they should now be kept growing on in an intermediate house, and placed in a light position as near the glass as possible.

Now that seed lists are to hand, an early opportunity should be taken to make a selection of those seeds required during the coming season and dispatch the orders as early as possible. In the flower garden much can be done with annuals if this be necessary, and, indeed, if other subjects are deficient, there are among annuals material for effectually filling beds with flowering plants that vie in effect with others that have entailed trouble and house room to preserve them through the winter. With the assistance of a few manure beds and frames, details of which will be given in due time, it is possible to make up a bright flower garden with these only, and as accessories to other arrangements and for use as cut flowers, some should be included in all flower garden arrangements. Among others verbenas, antirrhinums, double and single zinnias, gaillardias, phlox Drummondi, marigolds in variety, stocks and asters in great variety, pentstemons, scabious, salpiglossis, and Nemesia strumosa Suttoni may all be used for furnishing flower beds in summer, and most are also useful in a cut state. Small packets of the newer and much improved varieties of sweet peas may be bought, and with the great diversity of colours now attained, these form an indispensable subject where cut flowers are required. Lavateras, sweet sultans, poppies in variety, and many others are also desirable, while many important perennials may also be easily raised from seeds in spring. One of the latter now so much used, Gypsophila paniculata, the flowering sprays of which are so well adapted for mixing with other flowers, being so light and elegant, may be easily raised from seeds, and if sown early in spring make good flowering plants the second year.

Should inclement weather set in, take advantage of such to have all dirty pots washed up and stored in sizes in a dry place to be in readiness for the potting off of bedding stuff in a few weeks' time. Pegs may also be cut from old brooms for use in layering; crocks broken up and sifted into various size; while mowing machines needing repairs should be seen to without delay.—C. Herrin, *Dropmore Gardens.*

HARDY FRUITS.

The open weather enabled work in this department to be kept up to date, and there has been no delay in pruning. Currants, gooseberries, and other bush fruit may now receive attention. Gooseberries are usually left to the last if birds are numerous, as these are fond of the buds and do much mischief, but I think the best plan is to prune, and afterwards give the bushes a dressing of quassia extract with sufficient lime added to make it adhere to the branches; the quassia is very bitter and not relished by small birds, the lime also is useful in killing moss and cleansing the trees. After pruning it is a good plan to remove the old surface soil and give a dressing of new soil, manure and bone meal, as in many gardens these fruits often suffer for want of food. Failing new soil a good mulch of decayed manure now would do much good. In pruning the Lancashire varieties it is necessary to adopt a different course to that practised with the smaller kinds, as these trees make a weeping growth and lose wood; here, thinning may be done but a goodly portion of new wood must be retained, and in pruning it is best to cut away those growths near the soil and on which the fruit would be gritty. Where gooseberries are much in demand they are well worth special culture, and splendid results may be obtained by giving the trees support, and protecting with wire netting. North walls, often bare, may with advantage be planted up with gooseberries, but for that mode of growth I would advise the smaller berried varieties that are noted for their high flavour, such as the Green Gage, Crown Bob, and Champagne. These gooseberries, grown as double cordons and spurred hard back, bear splendid crops and are readily protected, when the fruit will hang a long time. Where currants have not done well it is advisable to make new quarters for them. Black currants sometimes have a peculiar disease the gall mite, which is difficult to get rid of, indeed, I have found it best to burn infested trees and plant new ones as far away from the old site as possible. Red currants have of late years received more attention, there are some fine berried kinds now and Fay's Prolific and Reine Victoria are improvements on the smaller kinds. It well repays cultivators who need good fruits, and in quantity, to plant a new quarter occasionally as the soil soon becomes impoverished, while the introduction of a new variety is advantageous.

Raspberry canes may now be shortened and made trim for the season. Raspberries are most profitable, given good culture. I am not impressed with the plan at times advised of growing the raspberry in the shade or under trees. The best fruits are those on canes given free exposure, and though shade may be advisable for late fruits, I would prefer a north border and an open position. Like the other bush fruits named, the raspberry is a surface rooter, and the more it is fed from the surface the better, so that a mulch of decayed manure given now is beneficial, and in places where liquid manure is running to waste, these trees may with advantage have a supply, as it cannot often be afforded them during growth. Raspberries attended to after fruiting will need but little pruning; avoid crowding and leave three strong canes to a stool. The supports should be renewed if necessary and the roots mulched; the latter may be done at a later period, but it is advisable to do any work now that will save time later. Worn-out raspberry stools may be rooted up and a new plantation made, for the advice given for the other fruits is just as applicable here. Among varieties I have found Superlative a profitable introduction; it produces a fine berry, somewhat later than others, but it never fails in seasons of drought, and is a grand fruit for poor, stony soils. Newly planted canes should be cut down to within nine inches of the soil before new growth commences. The autumn fruiting kinds are worth space, and these planted now will be in condition next year to crop; they are treated differently to the summer fruiters, being cut down in February, and they fruit in new wood. Strawberries in light soil may now receive a mulch of decayed manure; given at this season it will encourage early root action and strong blooms. Of course, this advice is not intended for small plants put out late, but those with ample growths. Small plants after severe frost often have their roots exposed, and so firming the plants would be beneficial, and I find a mulch of light material, such as old mushroom-bed manures assists them greatly. Strawberry quarters not manured should be Dutch hoed in dry weather, raking up the weeds and cutting away leafage in a decaying condition.—G. WYTHES, *Syon Gardens*.

Flowers and Insects.—I was much interested in Professor Plateau's observations in relation to flowers and insects, because they not only affirm my own opinion but also oppose the too common and somewhat empirical opinion that colour in flower petals specially attracts insects. If in our gardens we need evidence of the absurdity of the latter idea we find it easily enough in mignonette, there being no common garden flower which attracts insects, and especially honey bees, so largely as this unpretentious flower does. That attraction is due to its rich perfume and its honey deposits. But are not perfume and honey almost identical? Generally the sweeter the perfume the greater the honey store. White clover, heather, and lime, all inconspicuous-flowered plants or trees, are rich in honey secretions, and all are richly perfumed. Brilliantly-coloured flowers, such as roses, begonias, pelargoniums, and many others are rarely visited by honey bees or smaller insects, but some moths frequent them, just as they do single dahlia flowers, and soon become intoxicated with saccharine; or they care for giant sunflowers, attracted by sugar secretions, but not by the rich-coloured petals. One of our most beautiful blue garden flowers, Salvia patens, is largely visited by wild bees in search of sugar, but the insects do little to aid fertilisation in the process, because they bore holes in the flower tubes to extract the sugar rather than enter the flower mouth. Before it is further attempted to show that insects are attracted to flowers to aid fertilisation through rich-coloured petals, it must be shown that insects possess colour sight. So far it has been concluded that they have. Certainly they seem to possess remarkable power of smell, but to assert that they have equal capacity to be attracted by bright colours would be a larger order indeed.—A. D.

Cactus Dahlias.—In publishing the list of these flowers, now so wonderfully popular with all classes, which appears on page three, the secretary of the National Dahlia Society has rendered useful service to growers, because there are myriads of dahlia fanciers outside the ranks of the society who fail yet to understand the distinctions which exist between recognised cactus varieties and those commonly termed decorative. But I do not fully understand whether the list published is intended to be so far conclusive that none others can be, for the present year, admitted as cactus varieties at the society's exhibition. That is important to know; of course any varieties that show cactus form in an inferior degree to that found in those included in the list would but weaken a stand. None the less, some growers may chance their inclusion, and no doubt they would like to know beforehand whether such inclusion would disqualify. Then every year sees new introductions of varieties that evidence the ideal cactus form more fully than others. Is the society prepared to keep the scheduled list of recognised varieties to say fifty (the present list is forty-eight), the committee every year weeding out the most inferior and including the recognised best or improvements? Is not a recognised list of fifty, always including the best, enough and almost more than enough for all purposes? Again, if better forms are being constantly added, what good are inferior ones to either trader or exhibitor? To have an annual select list of that description, would be indeed a blessing to all interested in the cactus dahlia, as it would keep varieties within reasonable limits. But there should be a condition imposed on all exhibitors, trade or others, that neither old varieties expunged or seedling varieties not yet included should be eligible to compete in ordinary classes, and let there be a class for seedling varieties if desired, but certainly in other competitions trader and amateur should stand on the same footing.—A. D.

R.H.S. EXAMINATION IN HORTICULTURE.

As we are so frequently receiving letters asking for information concerning the annual Examination in Horticulture conducted by the Royal Horticultural Society, we now publish the rules and regulations for that function, as contained in the most recent issue of the society's *Journal*:—

1. The Council of the Royal Horticultural Society, sympathising with the efforts of various County Councils, technical institutes, schools, gardeners' mutual improvement societies, and other bodies to promote instruction in practical horticulture by means of lectures, demonstrations, &c.; and in the hope of rendering such teaching more definite and effective, have consented to hold an examination in horticulture on Tuesday, April 5, 1898.

2. The following is an outline syllabus, showing the nature of the subjects to which it is considered desirable that the attention of students should be drawn.

Elementary Principles.

On which Horticultural practice is based.

1. Soils, good and bad: Their nature and composition: Weeds and their eradication.
2. Requirements of growth—water, heat, air.
3. Seeds: Nature of, duration of vitality in, and modes of germination.
4. Roots: Nature and functions of; fibrils and root-hairs; what they do, and how they do it—what helps and what hinders them.
5. Stems and branches: Their nature, work, and uses; helps and hindrances to their work.
6. Leaves: what they are, what they do; helps and hindrances to their work.
7. Tubers and bulbs, leaf buds and flower buds.
8. Growth and development: increase in size and changes of composition and structure; formation and storage of food materials.
9. Flowers: their component parts; what they do; artificial fertilisation.
10. Fruit: Changes and development during ripening; forms and varieties, as, *e.g.*, apple, strawberry, plum, &c.
11. Seed: Formation of.
12. Variation and selection.
13. Names and orders of common garden plants, trees, &c.

Horticultural Operations and Practice.

1. Surveying and landscape gardening: Elements of.
2. Choice of site for garden.
3. Description and use of implements under each head.
4. Operations connected with the cultivation of the land, with explanations and illustrations of good and bad methods: digging and trenching; draining; hoeing, stirring the soil, and weeding; watering; preparation of seed beds; rolling and raking, sowing, transplanting and thinning; potting, planting; aspects, positions and shelter; staking; earthing and blanching, &c,
5. Propagation. Elementary principles: Cuttings, budding and grafting, stocks used, layering, division, branch pruning, root pruning; old and young trees and bushes. Training.
6. Fruit Culture: Open air and under glass; small fruits; apples and pears; stone fruits; gathering and storing; packing and marketing. General knowledge of fruits, and selection of varieties.
7. Vegetable culture: Tubers and roots; green vegetables: Fruits and seeds; rotation of crops, and selection of varieties.
8. Flower culture, outside and under glass.
9. Manures and their application.
10. Improvement of plants by cross-breeding, hybridisation, and selection.
11. Arboriculture: Trees and shrubs and their culture.
12. Insect and fungus pests: Prevention and treatment.

3. Students and young gardeners not having had the advantage of attending lectures, but wishing to present themselves at some one of the centres for examination, might with advantage consult some of the following works: "Primer of Botany" (Macmillan and Co.), by Sir J. D. Hooker, K.C.S.I.; "Botany for Beginners" and "Plant Life" (Bradbury, Agnew, and Co.), by M. T. Masters, M.D., F.R.S.; "Popular Gardening," four volumes (Cassell and Co.), edited by D. T. Fish; "Epitome of Gardening" (Adam Black and Co.), by T. Moore and M. T. Masters; "Agriculture," parts one and two (John Murray), by W. Fream, LL.D.; "Prize Essay on Fruit Culture," by J. Wright: "Physiology of Plants," by Professor Sorauer (Longmans, Green, and Co.): "Structural Botany," by Dr. D. H. Scott (Adam Black and Co.); "Natural History of Plants," by Kerner and Oliver (Blackie and Son).

4. The examination will be held simultaneously in as many different centres in Great Britain and Ireland as circumstances may demand.

The examination will for the most part be based on the above outline syllabus of "Elementary Principles of Horticultural Operations and Practice," but arrangements will be made, as far as possible, to frame the questions so as to cover the ground of any syllabus sent up for that purpose. It will, however, in all cases, be absolutely essential for students to exhibit a sufficient knowledge of the "Elementary Principles" named in the above syllabus.

6. Three hundred marks will be given as a maximum. Candidates gaining 200 marks and over will be placed in the first class. Those gaining 150 to 200 will be placed in the second class, and those gaining between 100 and 150 will be placed in the third class. Candidates failing to obtain 100 marks will not be classed.

7. The Royal Horticultural Society will award a Silver Gilt Medal to the candidate gaining the highest number of marks, and will also, if the County Council or other body promoting the lectures wish it, deliver to their candidates certificates of the class in which they shall have passed.

8. County Councils, lecturers, &c., must send in to the Society the actual number of candidates at each proposed centre at least ten days before the examination takes place.

9. Gardeners and students wishing to sit for the examination, but who have not attended any particular series of lectures, must send in their name and address, and also the name and address of some responsible person willing to conduct the examination (see par. 14), to the Secretary, R.H.S., 117, Victoria Street, Westminster, at least three weeks before the date of examination.

10. A small capitation fee of 3s. will be charged for every student, in order to partially defray the expenses of the examination.

11. County Councils, lecturers, and others desiring to have an examination held in their neighbourhood, must also send in the full name and address (with designation or occupation) of one responsible person for each proposed centre, who will undertake to supervise the examination in accordance with the society's rules.

12. The society is also willing to hold an examination wherever a magistrate

clergyman, schoolmaster, or other responsible person accustomed to examinations will consent to supervise one on the society's behalf, and in accordance with the rules laid down for its conduct.

13. A stamped and directed envelope must be enclosed with all communications requiring a reply.

Scholarships.

Sir Trevor Lawrence, Bart., President of the Society and Past Master of the Worshipful Company of Gardeners, very kindly offered a scholarship of £25 a year for two years, to be awarded, after the examination of the Royal Horticultural Society in 1895, to the student who should pass highest, if he were willing to accept the conditions attaching thereto. The main outline of these conditions is that the holder must be between the ages of eighteen and twenty-two years, and that he will study gardening for one year at least at the Royal Horticultural Society's Gardens at Chiswick, conforming to the general rules laid down there for students. In the second year of the scholarship he may, if he likes, continue his studies at some other place at home or abroad which shall be approved by the Master of the Worshipful Company of Gardeners, and by the Council of the Royal Horticultural Society.

A similar scholarship was presented by Baron Schröder, V.M.H., after the 1896 examination.

Another was given after the 1897 examination by N. N. Sherwood, Esq., V.M.H., Master of the Worshipful Company of Gardeners.

Another similar scholarship has been kindly promised for 1898-9 by G. W. Burrows, Esq., a member of the Court of the same Worshipful Company of Gardeners.

And yet another is promised for 1899-1900 by the Right Hon. the Lord Amherst.

If the student who is at the head of the examination is for any reason unable or unwilling to accept the scholarship, it is then offered to the next highest on the list, and so on throughout the first class.

NEW PLANTS, FLOWERS, AND FRUITS.

Camoensia maxima.

A handsome leguminous plant, and a strong growing West African climber with woody stem. The trifoliate leaves have leaflets three to six inches long, elliptic, oblong, pointed and dark green. The flowers are of large size, sweet-scented, white, with golden margins to the segments. Some idea of their size will be obtained from the statement that the calyx tube is six or seven inches long; the sepals are green. The petals are the chief attraction, and the standard is three to four inches across, and concave. The wing and keel petals are considerably smaller, but still large and attractive. Racemes bearing sixteen to eighteen flowers have been produced in the Edinburgh Botanic Gardens. Seeds of Camoensia maxima were received at Kew in 1873, they germinated freely and plants were widely distributed; the first to flower was a specimen sent to Trinidad, it flowered in 1882; a second, flowered in Ceylon in 1894; a third, at Mythe Castle, Tewkesbury, in the same year; a fourth, at Kew in November, 1896; and a fifth, at Edinburgh in 1897. The Kew plant also flowered again at the close of last year. *Bot. Mag.* t. 7,572.

Strobilanthes Dyerianus.

This fine addition to our handsome foliaged stove plants is a native of Burmah, where it appears to have been found by Boxall, a well-known collector in the employ Messrs. Hugh Low and Co., Clapton. Mr. Boxall gave specimens to the Singapore Botanic Gardens, and from thence some were sent to Kew in 1892. Young plants were duly distributed, and one was exhibited at Ghent in 1893 by Messrs. Sander and Co., St. Albans, who gave it the name it now bears. Since that date S. Dyerianus has become immensely popular for grouping, for table decoration, and almost all uses to which plants are put by gardeners. It is an acanthad and closely allied to the ruellias. It has elliptic-lanceolate leaves measuring six to eight inches long; these are bright green with bands of rose between the nerves, the whole having a satiny lustre or silvery sheen; the lower surface is rosy purple. By the time they flower the plants are apt to become leggy, but the erect spikes of pale violet-blue flowers are very pretty. A figure showing foliage and flowers is given in the *Bot. Mag.* t. 7,574.

Chrysanthemums.

Phyllis Fowler; incurved, a fine large yellow variety with broad but pointed florets. A bold flower, and with a distinct shade of colour. F.C.C., N.C.S., December 7, 1897. Mr. T. Robinson, gardener to W. Laurence, Esq., J.P., Hollingbourne.

Red L. Canning is a deep chestnut-red variety of the old L. Canning; it is a very bright, free-flowering, and useful market variety. Commended as a market variety by the N.C.S. on December 7 last. Mr. M. A. Felgate, Henley-on-Thames.

Cattleya Trianæ Sanderæ.

A charming variety, with palest blush-tinted sepals and petals, and a fine violet purple lip. The petals are very large and prettily frilled along the margins. The throat of the lip is yellowish orange, and the purple apex has a wire-edge of rose running along the marginal frill. A.M., R.H.S., January 11. Messrs. F. Sander and Co , St. Albans.

Lælia anceps Amesiana Crawshay's var.

A very pretty form and remarkable for the crimson purple front lobe of the lip, and the crimson markings in the throat. The sepals are pale rose, tinged purple; petals broad, deep rose shading to deep purple at the tips. The outer side of the side lobes of the lip are greenish, but the tips and margin are deep purple. Disc large and bright yellow; front lobe intense crimson purple. A.M., R.H.S., January 11. Mr. S. Cooke, gardener to De B. Crawshay, Esq , Rosefield, Sevenoaks.

Cypripedium F. H. Roberts.

A particularly handsome hybrid, obtained by crossing C. niveum with some other species not recorded (probably C. Curtisi). It is an interesting form with a white and broad dorsal sepal, shaded with rose at the base, and veined with rose. Petals very broad, slightly turned back at the tips, and similarly coloured as the dorsal sepal with additional spottings or tiny dottings of dark purple. The lip has the rounded opening seen in C. niveum, but is longer, deep rose veined with darker rose, and with a whitish base. The flower is about three and a half inches across. A.M., R.H.S., January 11. Messrs. Hugh Low and Co. Clapton.

Pear President Barabe.

A productive mid-winter variety of continental origin, with rather small turbinate, deliciously flavoured fruits. The Fruit Committee on rising left one fruit intact, but this disappeared, and a core and stalk with a scrap of rind were the only materials from which visitors could form an opinion of the variety. F.C.C., R.H.S., January 11. Mr. W. Allan, Gunton Park.

EXHIBITIONS AND MEETINGS.

ROYAL HORTICULTURAL SOCIETY, January 11.

A month ago we reported the last R.H.S. meeting of 1897, now we have to record the first for the year 1898. This, however, is the last meeting of the R.H.S. year, for the February gathering and annual meeting closes one year and commences another. The present display was a very fair one, not so large as some of the January exhibitions have been, but still of great interest. Orchids were not largely represented, and only three novelties were considered worthy of award. Cyclamen and primulas made up the bulk of the show, and were very well grown. Fruit was good for so late a date, and Mr. Bury's grapes were a great source of attraction and interest.

Floral Committee.

Primulas and cyclamen were both abundant and good; stove plants were staged in good condition, but novelties were very few, and none gained awards.

An effective exhibit of foliage and flowering plants, staged by Messrs. J. Laing and Sons, Forest Hill, merited a silver Flora medal. Palms, dracænas, crotons of high colour, foliage begonias, nepenthes, Leea amabilis, Miconia magnificum, Phyllotæium Lindeni, Rhyncospermum jasminoides variegatum, aralias, cyclamen, and Begonia Gloire de Lorraine were the most conspicuous plants in an interesting display. A fine display of primulas came from Messrs. H. Cannell and Sons, Swanley; nearly two hundred plants were staged, and the majority were single forms in about twenty-four varieties. Some of the specimens were scarcely at their best, but the exhibit was a fine one, serving admirably to show the carefulness with which the Swanley firm have selected and perpetuated their strains. Some particularly attractive sorts were White Perfection, Swanley Blue, Eynsford Red, very bright; Swanley Yellow, white, with a very large deep yellow central area; and Emperor Improved, a very bright and large rose form. The firm was awarded a silver Flora medal for these singles, and a few good specimens of Marchioness of Exeter, a handsome double white. Cyclamen from Messrs. H. Low and Co., Clapton, were a fine display, the coloured forms were bright and varied, while the white varieties were remarkable for their purity and profusion of flowers. A small batch of Winter Scarlet carnation, a brilliant tree variety, also came from Clapton; a medal was awarded.

Messrs. Sutton and Sons, Reading, staged a splendid lot of cyclamen, arranging the neat and freely-flowered specimens in batches of one colour. The whites were very fine, and afforded good contrasts with Vulcan, Salmon Queen, Giant Purple, Giant Rose, and Giant Crimson and White, which were all greatly admired; silver Flora medal. Mr. J. R. Box, Croydon, secured a silver Flora medal for a good exhibit of single primulas. The plants were in every instance large, well grown, and freely flowered, most of them carrying three to six handsome trusses. About a hundred specimens were staged in fifteen distinct varieties. A few of the most attractive were Princess Mary, pure white; Surprise, bright rose pink, much frilled; Firefly, very rich scarlet; Rosamond, deep purple; White Perfection, white, and much fringed and frilled; and Mrs. Periera, a porcelain-blue shade.

Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, showed four pans of the charming Narcissus monophylla and Fritillaria oranensis. Some finely-flowered sprays of the sweet Chimonanthus fragrans were sent by Mr. F. W. Moore, the Botanic Gardens, Glasnevin; Mr. Moore also sent Iris stylosa var. Empress Elizabeth, a very bright purple form. Dracæna Distinction, from Messrs. J. Laing and Sons, is a graceful narrow-leaved form. A curious dracæna from Mr. Empson did not meet with much approval owing to its pure green leaves. A tray of Javanico-jasminiflorum hybrid rhododendrons came from Messrs. J. Veitch and Sons, Chelsea; these were remarkably bright, and showed in a wonderful degree their usefulness for a variety of purposes at this dull season of the year. Especially attractive were Minerva, Monarch, multiflora Neptune, Thetis, Sybil, Ceres, and luteo-roseum. This firm also sent baskets of flowering sprays of Garrya elliptica, Hamamelis japonica Zuccariniana, and H. arborea.

Orchid Committee.

This body soon dispatched the business brought before it, for novelties were scarce and the groups were small. There were several interesting orchids, and Captain Holford sent a fine lot of cut blooms of cypripediums that deserved to be staged in a much more attractive manner than merely placing half-a-dozen in an earthenware vase.

From Messrs. F. Sander and Co., St. Albans, came a small collection of orchids arranged with the graceful Dracæna Godseffiana; Lælia anceps Dawsoniana, L. a Sanderiana, and L. a Hilli were each represented; Lycaste Skinneri in good variety, and several hybrid cypripediums were also shown. Messrs. H. Low and Co. showed Odontoglossum crispum Jackianum, a yellowish form, O. Halli in variety, O. Andersoni, Cypripedium Germinyanum, C. Spicerianum, C. Lathamianum, C. Bellona, C. F. S. Roberts, a new and pretty niveum cross with white segments marked with rose and purple. Mr. T. Stafford, orchid grower to F. Hardy, Esq., Tyntesfield, near Manchester, showed an example of the rare Cypripedium insigne Sanderæ, a good form with one large flower: also a spike of Odontoglossum Andersonianum, a moderate variety.

Mr. Chapman, gardener to Captain Holford, Westonbirt, Gloucestershire, was awarded a silver Banksian medal for a group of cut orchids; a remarkably good lot of cypripediums were staged, including C. Niobe superbum, C. Leeanum, Albertianum, C. Pitcherianum Williams' var., and C. insigne citrina; Lælia autumnalis in variety was also well shown. Mr. J. Carr, Twerton-on-Avon sent some flowers of Cypripedium Boxalli atratum crosses all showing the influence of this parent. Mr. F. A. Rehder, Gipsy Hill, showed Cypripedium Rehderianum a curious dark purple and white form, whose parentage was not recorded.

Fruit Committee.

Mr. J. Bury, Petersham Vineries, Byfleet, Woking, was awarded a silver Knightian medal for a handsome lot of grapes staged on boards, in a tray, and in baskets ready for carriage to market; the varieties were Muscat of Alexandria, Black Alicante, and Gros Colmar, and all were splendidly coloured. Mr. J. Miller, Ruxley Lodge, Esher, merited a cultural commendation for a fine lot of mushrooms. Messrs. T. Rivers and Son, Sawbridgeworth, showed a fruiting branch of a citron bearing four splendid fruits; this firm also sent Directeur Tisserand and Mrs. Pearson grapes; well kept. A silver Knightian medal was awarded Mr. W. J. Empson, gardener to Mrs. Wingfield, Ampthill House, Bedford, for a collection of apples and pears. There were fine examples of Lord Derby, Ribston Pippin, Beauty of Kent, Cox's Orange Pippin, Mére de Mènage, Baumann's Red Winter Reinette, Tower of Glamis, and King of the Pippins.

Mr. C. Ross, Welford Park Gardens, Ross, gained the Veitch prize for the best flavoured pear with Josephine de Malines. Colonel Brymer, M.P., Dorchester, was placed second for apples with Claygate Pearmain. So far as we are able to discover no other prizes were awarded.

THE YORKSHIRE GALA.

On the 7th inst. the annual meeting of the guarantors and life members of the Grand Yorkshire Gala was held at Harker's Hotel, York. There was a large attendance, and Alderman Sir Joseph Terry presided. After reading letters from several influential members regretting their inability to be present, the Chairman, alluding to the gala held in June, 1897, said that circumstances had prevented the public witnessing the usual beautiful floral exhibition. He believed the flower show would have been of an exceptional character, and one which would have been immensely appreciated. A strong wind, however, on the morning of the fête wrecked the flower tents, and rendered all the perfected arrangements but work in vain. The damage done amounted to about £600, a catastrophe which had never been previously experienced. On every hand the circumstances had created regret. Expressions of sympathy had been received from several of the exhibitors, and one gentleman—Mr. Atkinson, of Sheffield—had sent a donation of five guineas to the society. He sincerely hoped that they might never again experience like conditions. The ensuing year, he trusted, might be one of an unexampled character, and make up for the loss they had sustained twelve months ago. As regarded the coming fête they had again made satisfactory arrangements with the Bootham Asylum authorities. Other pleasing circumstances were that the Lord Mayor (Mr. Edwin Gray) and the City Sheriff (Mr. Harold Copperthwaite) had been elected life members, and the Lord Mayor had consented to become president for the current year. He proposed that his lordship be so elected, and the proposition was carried.

Alderman Sir Christopher Milward proposed the re-election of Sir Joseph Terry as chairman of the council, who, he said, had devoted a great deal of time and service in the interests of the gala. He had been associated with the fête for many years, and had always taken great interest in its welfare. He was sure the meeting would also join with him in congratulating Sir Joseph on the fact that he had that day reached his seventieth birthday. He was sure it was a pleasure to the citizens to see him so hale and hearty, and able to discharge his many important duties. They also rejoiced that he was in improved health, and hoped that he might be spared for many years to come. The motion was heartily approved. Alderman Border proposed that Sir Christopher Milward be elected vice-chairman. Sir Christopher Milward, however, demurred to that course, and stated that, having been ordered complete rest, he could not undertake the duties. Eventually Mr. Border consented to stand again, and was unanimously re-appointed. Other officers appointed were: Treasurer, Mr. Joseph Wilkinson; secretary, Mr. C. W. Simmons; and auditors, Messrs. Pearson and Taylor. The usual committee were also elected.

The following grants were made for the ensuing gala: Floral arrangements, £650 (including £50 as a Victorian commemoration prize, offered last year but not awarded); music, £200; fireworks, £100; amusements, £150; balloons, £60. On the proposition of the Chairman, seconded by Mr. Alderman Border, votes of condolence were presented to the families of the late Sir Frank Lockwood, Q.C., M.P., Mr. T. P. Bulmer, J.P., and Mr. Geo. Dennis. Alderman Purnell proposed a vote of thanks to Sir Joseph Terry, and, Sir Joseph having suitably responded, the meeting ended.

READING GARDENERS' ASSOCIATION.

The annual general meeting of the Reading and District Gardeners' Mutual Improvement Association was held in the club-room, British Workman, on Monday last, when Mr. C. B. Stevens presided over a good attendance of members. The report and balance sheet read by the hon. secretary, Mr. James Pound, jun., were of a very satisfactory nature, both showing that the association was in a very flourishing condition. The membership was still on the increase, thirty-one new members had been elected during the year 1897, making over 180 "paid up" members on the books, whilst the balance in hand was double that at the end of 1896. The committee regretted the death of Mr. Alfred Sutton who had always taken a great interest in the work of the association, and had, since its formation in 1888, provided gratuitously the club-room for their meetings. They also record the death of Mr. George Palmer, who was an annual subscriber rom the commencement of the association. The meetings during the year had been well attended, on some occasions upwards of eighty members being present, and with the subjects so varied and interesting, such as Soils; Insects injurious to plant life; Table decorations; Summer Bedding; Zonal Pelargoniums; Bees as friends and enemies of the gardener; Kitchen Garden Work; Tomatos, and their diseases; The Balsam; Fruit Growing; Sweet Peas; Some Types of Insect Pests; A Chat about Chrysanthemums, &c., much benefit and help must have been attained by meeting together. The thanks of the committee were due to the president, Mr. C. B. Stevens, for the great interest shown not only in presiding at their meetings but taking an active part in all the other business connected with the association; to Messrs. Sutton and Sons for their kindness in providing a room at the Abbey Hall for the use of the members, and supplying it with horticultural and other literature; to the honorary members for their kind and general support; to those who have helped forward the work by reading papers and introducing subjects for discussion; to those who have added so much interest to the meetings by bringing exhibits of flowers, &c.; and last, but not least, to the horticultural and local press for publishing reports of the meetings. After the report and balance sheet had been adopted, the following were elected to fill the various offices during the coming year: President, Mr. C. B. Stevens; chairman, Mr. T. Turton; vice-chairman, Mr. G. Hinton; librarian, Mr. J. Martin; assistant librarian, Mr. E. Dore; treasurer, Mr. W. Phipps; hon. secretary, Mr. J. Pound, jun.; committee, Messrs. F. Bright, C. Burton, R. Butcher, R. Chamberlain, H. G. Cox, B. Dockerill, H. Farey, W. Goddard, F. Lever, T. Neve, J. Pound, G. Smith, W. Smith, W. Townsend, H. Wilson, and J. Woolford; auditors, Messrs. F. Tufnail and A. Smith; whilst Messrs. Cox and Woolford were elected to represent the association on the Reading Horticultural Society, and the Reading Chrysanthemum Society. A beautiful group of well-grown cyclamen was shown by Mr. W. Townsend, The Gardens, Sandhurst Lodge, noticeable being Sutton's Butterfly, Vulcan, Salmon Queen, and Giant White varieties.

LEE AND BLACKHEATH HORTICULTURAL SOCIETY.

The annual meeting of this society was held at the Lee Institute on Monday evening, Mr. M. N. Buttanshaw (the treasurer) in the chair. There was a larger attendance than for some years past. The following report was presented by the committee:—

The show, held on July 7 and 8 last, was a fully representative one, and the exhibits generally were highly satisfactory. The weather being fine, there was a larger attendance than there had been for some years past. Roses were shown in very large numbers and good form. Groups—not for competition—by leading nurserymen formed, as usual, a pleasing addition to the exhibition. The committee regret that, chiefly through the apathy shown by the residents of the neighbourhood, the subscriptions have again fallen off, and it has been deemed advisable to reduce the prize list for the present, in order to lessen the expenses, so that, if possible, in the coming years the debt may be materially reduced, and not increased, as has been the case in the present and preceding years. A new feature of the exhibition—a flower stall—suggested by one of the committee, was a decided success, and the lady and gentlemen gymnasts were a great attraction. Hearty thanks are due to Mrs. Penn (for the use of her grounds), to the president (Mr. J. Penn, M.P.), to Mr. M. N. Buttanshaw (the treasurer), and to all the special prize givers. The lectures, now in course of delivery at the monthly meetings of the winter session of 1897-8, are not being so well attended as they might be, and lecturers can hardly be expected to come again unless better encouraged. The dates fixed for the 1898 exhibition are Wednesday and Thursday, July 6 and 7.

After some discussion the report and balance-sheet were adopted.

SUNDERLAND AND DISTRICT GARDENERS' ASSOCIATION.

This flourishing society held its seventh annual dinner a few days since at the Palatine Hotel, when upwards of sixty sat down. The President Councillor Roche occupied the chair, and was supported by the Rev. Dr. Randall, vice-president. After the usual loyal toasts had been duly honoured, Mr. T. W. Bolam, F.R.H.S., chairman of the society, proposed the toast of the "President and Vice-Presidents." Councillor Roche, in responding, said he was much gratified by their having again chosen him to be their president. He believed the profession of a gardener was one of the oldest, and was pleased to be able to say that their society was a strong and influential one, and was advancing by leaps and bounds. The year was begun with a satisfactory balance, and ended with a more satisfactory one, which promised well for the future. He had pleasure in asking them to accept Professor Von Kerner's new work—the "Natural History of Plants," for their library. Dr. Randall also responded, and next proposed success to the society. He said it deserved a far more enthusiastic support and encouragement than it was possible for him to give it, but so far as he had the power he should do everything he could to ensure its prosperity, success, and development, for, if there was one useful movement in Sunderland unconnected with his own profession, it was that represented by the Gardeners' Society. The society had a record, its work would bear investigation; it was a record of which such a young society might well be proud. The annual report grew year by year, and an increasing membership availed themselves of the advantages it offered. He noted the fulfilment of the hope expressed last year, that there should be an interchange of visits and papers between their society and that of Newcastle, and he thought this might possibly be extended to other neighbouring towns. A society that could bring together such a meeting as the one before him was worthy of support and prosperity. One feature of the meeting was that it was composed both of veterans in the profession and smart, promising young men. An excellent feature of the society was that it brought together men of all ages and ranks in the profession, enabling the youngsters to lay hold of the gathered experience of the older ones, and helped the older ones to lay hold of the bright and brilliant ideas of the younger ones. Mr. W. Hall, F.R.H.S., thanked the president for his present of books, and spoke of the work accomplished during the year.

"The Honorary Members" was proposed by Mr. Brunton, and responded to by Mr. Bolam. He said if the society received the same support in the coming year as in the past from the honorary members, they would be able to reduce the membership fee, which would tend to increase the number of amateur members. Mr. J. T. Richardson proposed "The Press," which was responded to by the representatives. Dr. Randall, Mr. C. Donkin, Mr. R. D. Jeffrey, Mr. James Weymms, and Mr. W. Thompson contributed to the evening's harmony with songs, &c.

The present flourishing condition of the society is in a great measure due to the chairman (Mr. T. W. Bolam) and to the secretary (Mr. J. Watson); the former has taken a deep and active interest in its work since its formation, and, as showing the esteem in which he is held by the members, has been unanimously elected chairman six times out of the seven years of the existence of the society.

ISLE OF WIGHT HORTICULTURAL ASSOCIATION.

A highly satisfactory report was presented by Mr. S. Heaton at the annual meeting of the above association, as will be gathered from the following summary: The committee of the association have great pleasure in presenting to the members a report of a full and satisfactory year's work. The balance in hand is not so large as it was last year. This is mainly due to the extra expense incurred in providing certificates for meritorious exhibits at monthly meetings, at the cottage garden shows, and to the excursions which took place during 1897. The first excursion was to St. John's Vicarage Gardens, Ryde, on May 8, at the invitation of the Rev. H. Ewbank, M.A., F.R.H.S. Over fifty members avaited themselves of the opportunity of visiting this well-known garden, which contains rare plants in variety—many collected by Mr. Ewbank himself when travelling abroad. The second excursion took place on July 14 to Brooke House, the residence of Sir Charles Seely, Bart., who is president of the association. Between fifty and sixty members availed themselves of the opportunity of what proved a pleasant and profitable outing. Mr. Tribbick, F.R.H.S., received warm praise for a house of fine Muscat grapes, and for the general excellence of the gardens. Both Mr. Ewbank and Sir Charles Seeley entertained the members most hospitably, providing in each case an excellent repast. The third and last excursion of the season was to Swanmore Park, the residence of W. H. Myers, Esq., M.P. A thoroughly enjoyable outing was only marred by the want of more time to inspect the gardens so ably managed by Mr. E. Molyneux, V.M.H.

The Committee are fully conscious that certificates have been rather lavishly bestowed during the year, but the fact cannot be gainsaid that this little extravagance has stimulated the interests of horticulture, particularly in the villages, and made the association more popular and useful. During the year, twenty-nine certificates for cultural merit were awarded, fourteen certificates for new or rare exhibits, and four certificates of commendation, making a total of forty-seven. The Daffodil Exhibition held at the Medina Hall, Newport, on April 3, was greatly appreciated by the public, and upon the whole was very successful. At the October meeting the members staged over one hundred dishes of fruit, which was highly meritorious, and reflected great credit upon the growers.

The number of members is two hundred and eight, against one hundred and seven last year, which is a net gain of one hundred and one. Although everyone interested in horticulture is heartily welcomed at the meetings of the association, it is desirable, in the opinion of the committee, that its membership should be as large as possible. The subscription for vice-presidents is 10s. 6d. per annum, for honorary members 5s., and for ordinary members 1s. 6d.

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning change of dates

Weight of Bunches of Black Hamburgh Grapes.—J. F., Pontefract: So far as we are aware, the heaviest bnnch of Black Hamburgh grapes known was exhibited at Belfast in 1874 by Mr. Hunter, of Lambton Castle. This enormous specimen weighed 21 lb. 12 oz. The following year Mr. Hunter showed a bunch at the Manchester exhibition which weighed 13 lb. 2 oz. Bunches weighing 8 lb. or 9 lb. each have been recorded, but none approach in any way the famous examples produced over twenty years ago.

Cultivation of Erica hyemalis.—G. G., Torquay: Erica hyemalis is a somewhat soft-wooded and free-growing species as compared with many others, and thus, in the earlier stages of growth, more pinching is necessary if the object in view is a large specimen. It does not differ materially from the majority of heaths grown in gardens in its likes and dislikes, but being very robust, its growth is made earlier than in most sorts, and specimens can be placed out of doors at an earlier period than is recommendable for others. Growth must be thoroughly finished or flowers will not be abundant. It is a bad plan to stand the plants where the influence of the sun is directly upon the pots, for heaths like to have their roots cool. The pots must be shaded or plunged in some cool medium, such as fine ashes, where drainage is at the same time ensured. After flowering it is best to cut back the growths of this species, and to do so freely, otherwise the plants will speedily become tall and leggy; this remark applies equally to all the winter-flowering heaths.

Propagation of Isolepis gracilis.—M. M., Maidstone: It is best to defer the propagation of this pretty grass until the spring, when growth commences, for if the plants are divided at present damping is very likely to set in. Any fairly open soil will suit the species. Part up the old specimens, and place a little tuft in a three-inch pot; give a watering, and place in a temperature of 55 to 65 degrees. When well-rooted remove to the greenhouse, and as the pots will be by this time almost full of roots, it will be necessary to pot on into forty-eight-sized pots as soon as the plants are acclimatised. This size will be found large enough for most purposes, while it is good practice to keep some in sixties for small groups, &c.. The leading nurserymen offer seed of Isolepis gracilis, so that if you need an extra large stock it will be advisable to obtain a few packets besides parting up all the old plants procurable. The species is widely distributed throughout extra-tropical regions. Isolepis gracilis is but a common garden name for Scirpus riparius.

Andromeda.—G. E., Shrewsbury: Your supposition is quite correct; the genus Andromeda was founded by Linnæus, and the name was given because the famous botanist saw so many points of comparison between the type plant, Andromeda polifolia, and the lady whom Neptune chained, naked, to a rock. The story has previously been told in these columns, but it will bear repetition; it is charmingly told by Linnæus in his "Lachesis Lapponica," and continued in the "Flora Lapponica." Linnæus first saw the plant growing in marshy ground in Lapland, and described it as being most beautiful on the twelfth of June. While admiring the delicate colouring of the flower and the grace and elegance of the racemes, the story of Andromeda came to his mind. Andromeda, to appease the wrath of Neptune, was chained naked to a rock, and exposed to be devoured by a sea-monster. She was, however, released by Perseus, who afterwards marriad her, and by whom she had many children. The flowers of A. polifolia, says Linnæus, are blood-red ere they expand, but when fully-grown are of a flesh colour, like the beauty of a handsome female complexion, and such as no artificial colouring could produce. The great naturalist says that as he meditated upon the poetical descriptions of the exquisite and unrivalled charms of Andromeda, he became convinced that no better name than hers could be given to the plant before him. As Andromeda was chained to a rock with the sea running around her feet, so this plant is always fixed on a small hillock in the swamps with fresh water washing its roots. As this beautiful girl was surrounded by horrid and venomous monsters, so toads and other reptiles frequented the position of her vegetable resembler. The distress of Andromeda under such dire affliction would destroy many of her charms, and with little hope of rescue, her drooping spirits would find expression in a head bent down to hide her blushing face. "So," says Linnæus, "Does this rosy-coloured flower hang its head, growing paler and paler till it withers away." Continuing the fanciful and wonderful analogy in the second work quoted, he says, "At length comes Perseus; the water is dried up, the monsters of all kinds are destroyed or driven away, and Andromeda is rescued to become the wife of her saviour; as a handsome mother she once more holds her head erect without a blush of shame. Perseus is the summer, with its warmth and drying influence, when toads and other reptiles would naturally disappear from the dried-up swamp to moist situations. Fertilisation takes place, and the flowers wither away; but in the autumn the seed capsule, apparently conscious of its own importance in the work of giving continuity to the species, turns from its half-hiding, drooping position, and holds itself erect." When we understand the reasons for its application we are compelled to own that Andromeda is an apt name for the plant in question, and the story of Andromeda possesses an added interest when, through the words of the great Swedish naturalist, we draw a close analogy between it and one of our prettiest flowering shrubs. We trust that your andromedas will prove as successful as you could wish. We may add that one species you mention—A. floribunda—is now recognised as Pieris floribunda.

Scale on Peach Trees.—E. J. T., Isle of Wight: The best plan for removing this pest is to carefully clean every branch and twig, using fir-tree oil, or any other good insecticide. Commence by moistening the tree with warm soapy water, and then with a small label gently scrape the scales away, afterwards sponging the growths with the insecticide. It is a good plan to place some canvas beneath the trees while the work is being performed, so as to catch any scales that may fall. Beside the blunt label, it will be found useful to use a short, stiff-haired brush to remove the pests from joints and round the buds. A good deal of patience is necessary ere this work is brought to a successful conclusion, but on trees under glass it is eminently desirable that the pest be removed ere heat is applied and growth becomes vigorous. After a thorough cleansing, it will be advisable to frequently examine the trees to see whether any individual has escaped.

Bark Beetles.—S. C., Bishop's Stortford: The elms have been subjected to an attack of Scolytus Geoffroyi, one of the most destructive of the numerous bark beetles. It almost invariably happens that trees attacked are unhealthy, for the little pests prefers dead or dying to live and healthy trees. This being so, it will be necessary to discover whether anything can be done to improve the condition of the young elms, either by drainage or a good top dressing. Remove all damaged parts, and wash the stems with a tobacco water solution, taking advantage of any abrasions in the bark to forcibly inject some of the solution. During the summer the bark of all the trees should be frequently saturated with a tobacco solution so as to render the trees distasteful to the beetles. Where the holes are very apparent in the bark pieces should be removed about the end of June, as, if this be done, the larvæ will die and be eaten by birds. Pieces of dead elm bark may also be used as traps during the summer, but they should be renewed at least once a month, and the old ones burned.

Names of Plants.—Under this heading we can only undertake to name species and specific varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp moss or leaves as packing material to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that the numbers be legible and firmly attached to the specimens. We cannot promise to name more than six specimens at one time from any one correspondent.

A. S., Cheltenham: 1, Pentas carnea; 2, Erica hyemalis; 3, Pteris sagittifolia.

H. P. D., Woking: 1, Grevillea Thelymaniana; 2, Chimonanthus fragrans; 3, Dracæna rubra; 4, Lycaste Skinneri, a poor form.

W. B., Bristol: 1, Rhyncospermum jasminoides; 2, Libonia Penhrosensis; 3, Nephrodium denticulatum; 4, Rhododendron jasminiflorum.

S. F. J., Sale: 1, Jasminum nudiflorum; 2, Hamamelis arborea; 3, Maranta zebrina; 4, Mussænda frondosa; 5, Epiphyllum truncatum bicolor; 6, Coronilla glauca.

C. L., Retford: 1, Cestrum elegans; 2, Pellæa cordata; 3, Cheilanthes farinosa; 4, Pteris cretica nobilis; 5, P. scaberula.

A. S. G., Huddersfield: 1, Apparently a leaf of the Vanilla (*Vanill planifolia*); 2, Marcgravia paradoxa.

Stoking.—The frost that commenced on Wednesday, December 22 last, was very severe, and will, I expect, have done much damage, following, as it did, a particularly mild time. We were thinking of having a very easy Christmas time, but the reverse was the case. Where the water could be drawn out of the pipes and boilers all was safe, however. Those houses for which we only planned a little fire required far more than we intended even to keep the frost out. The full value of good boilers and good fuel was recently tested, when fires were lighted up and the heat raised in less than two hours; after that the heat was reduced by the damper. Next morning no stirring up of the fire was done, but it was fed with riddlings from the ash heap; this says much for the lasting and heating qualities of anthracite. The difficulty in this early firing for mid-season houses is in keeping only just what is required to be safe. Thus for an hour or two, with sun, we could do without fire; but we dare not, as heat would subsequently be lost. I have also found the utility of piping round the north end of houses, this being the weak point in many vineries. Expansion joints I believe to be the safest during sudden frosts should they get froze, for india-rubber rings will burst before the pipes. A good stoker is a jewel; by good I not only mean a man to raise the heat with full regard to value of fuel, &c., but one, also, who is clean in his work, and who, above all, looks well after his ash-heap. All our ashes are riddled, and the proportion of fine ashes is very small. This extra firing has necessitated more water about the borders near the pipes. One day and night of firing costs me as much as it did in a whole week of late, but I had to set two extra boilers going on account of the prominent vine buds, being afraid of frost; but I did not intend doing this until the new year had set in. The importance of a good stock of coal has been forcibly brought home to me, for to get a supply now would be impossible. With anthracite our fires are safely made up at tea time for lasting until next morning, though, of course, a visit to the houses is made nightly to see that all is right. Oiling of valves, air taps, &c., is a part of the stoker's duties, and this is important, for perhaps all will work well for a week, and then from some cause or other the heat will work up more one side than the other; then by a turn of the valve the alteration necessary is made. As boilers and flues are allowed to rest, and while they are warm, all are thoroughly cleaned, and now those standing idle are equal in appearance to new work, even after three seasons' firing. Fortunately, having a full pressure and supply of water for filling the pipes and boilers, we can well afford to empty our heating apparatus once a year. At the time of writing it really looks as if we were to have a spell of old-fashioned winter. The inconveniences are many, I know, yet I fully believe it is better for the general health; and if we spend more in firing now less will be required later on, and, of course, if vines are ready, with tomatos all right, all will be considerably earlier.—STEPHEN CASTLE, F.R.H.S., *Bottesford Vineries, Notts.*

"WHAT CANNOT BE CURED MUST BE ENDURED" need not be said to those who suffer from the effects of bad legs, scorbutic and scrofulous sores, as Holloway's Ointment and Pills are splendid specifics for these distressing afflictions. The earnest gratitude of thousands who have experienced the wonderful influence of these remedies, so that they have been raised from a position of prostrate helplessness to one ot independence and comfort, is being constantly expressed, both personally and by letter. Their value is known throughout the world for every form of disease. In cases of indigestion, ague, fevers and disorders of the stomach and bowels, the pills are an infallible remedy. For gout, rheumatism, neuralgia, &c., the Ointment is a blessing to thousands of poor sufferers.—[ADVT.]

OBITUARY.

SIR JOSEPH TERRY, for many years past chairman and influential member of the executive of the Grand Yorkshire Gala, died, we regret to inform our readers, at three o'clock on Wednesday morning, January 12. Sir Joseph will be greatly missed in the famous old city, where he was thrice elected Lord Mayor. A wider circle will also mourn his loss, for British horticulturists will deeply regret his decease. He was deeply interested in horticulture, and ever a prime mover in advancing its interest in and around York. Although 70 years of age on Thursday, the 7th inst., Sir Joseph was apparently hale and hearty, erect, business-like, and pleasant as usual on that date, for, as our columns testify, he that evening presided over the annual meeting of the Yorkshire Gala guarantors and members. As showing the high esteem in which he was held, we may add that a few years ago the exhibitors at the gala subscribed for a handsome testimonial which they presented to him as a token of their appreciation of his services in the cause of horticulture.

MARKETS.

Covent Garden.

THE demand for fruit is not large at present, but the shortened supply is equal to it. Vegetables of various kinds are plentiful, and there is a first-rate demand at prices with an upward tendency.

FRUIT.—English apples, 4s. to 15s. per bushel; American and Nova Scotian, 12s. to 35s. per barrel; English grapes, 1s. 3d. to 2s. 6d. per lb.; Almeria, 12s. to 20s. per barrel; bananas, 5s. to 10s. per bunch; pineapples, 2s. to 6s. each; pomegranates, 7s. to 9s. per case; Valencia oranges, 8s. to 15s.; Murcia, 6s. to 8s. per case; Jaffa, 9s. to 10s. 6d.; mandarins, 10d. to 1s. 6d. per box; French chestnuts, 6s. to 9s.; Italian, 12s. to 15s. per bag; French pears, 4s. to 6s. 6d.; Californian, 8s. to 12s. per case.

FLOWERS.—Arums, 4s. to 6s.; carnations, 1s. to 3s.; chrysanthemums, 1s. to 3s.; gardenias, 3s. to 5s.; eucharis, 4s. to 6s.; Lillium Harrisi, 4s. to 6s.; tea roses, 6d. to 1s.; pink roses, 1s. to 3s.; cattleyas, 6s. to 10s.; Odontoglossum crispum, 1s. 6d. to 4s.; and tuberoses, 3d. to 4d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; chrysanthemums, 6s. to 12s.; marguerites, 2s. to 4s.; mignonette, 2s. to 4s.; pelargoniums (scarlet), 6s. to 12s.; and violets, 1s. 6d. to 2s. per dozen bunches; azaleas, 9d. to 1s. 6d.; stephanotis, 4s. to 6s.; white narciss, 1s. to 2s.; Roman hyacinths, 6d. to 1s. 6d.; lily of the valley, 1s. to 2s.; and pelargoniums, 6d. to 1s. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 3s. to 4s. per bunch.

VEGETABLES.—Canary tomatos, 10d. to 1s. 6d. per tray; 4s. to 5s per case; asparagus, 4s. to 5s. per bundle; seakale, 12s. to 18s. per dozen punnets; horseradish, 12s. to 18s. per dozen bundles; French artichokes, 2s. to 3s.; lettuce, 9d to 1s.; endive, 1s. 6d. to 1s. 9d.; cucumbers, 4s. to 7s. 6d.; cauliflowers, 1s. to 2s. per dozen; beetroots, 2s. to 2s. 6d.; parsnips, 3s. to 3s. 6d.; cabbages and savoys, 3s. 6d. to 6s. per tally; English onions, 4s. 6d. to 5s. per cwt.; Belgian, 3s. to 3s. 6d. per bag; Valencia, 5s. to 6s. 6d. per case; forced rhubarb, 2s. 6d. to 3s. 6d.; carrots, 2s. to 3s.; turnips, 2s. 6d. to 3s. 6d.; parsley, 1s. 6d. to 2s.; greens, 2s. to 2s. 6d. per dozen bunches; mushrooms, 6s. to 8s.; eschallots, 2s. per 12 lb.; celery, 9s. to 15s. per dozen rolls; potatos, 65s. to 100s. per ton.

Borough Potato Market.

Business is very slow, but owing to the lightness of supplies, recent prices are obtained.

Dunbars, 115s. to 125s.; Hebrons, 90s. to 105s.; Snowdrops, 85s. to 95s.; Bruce, Maincrops, and Sutton's Regents, 80s. to 90s.; Reading Giants and Saxons, 80s. per ton; Belgians, 3s. 9d. to 4s.; Germans, 4s. to 4s. 3d. per bag.

The mean reading of the Barometer during the week at Greenwich was 29·86 inches, and that of the Thermometer 43°·4, the latter being 5°·1 above the week's average in the 50 years 1841—90. The direction of the wind was variable, the horizontal movement of the air being 25 per cent. below the week's average in the 16 years 1860—75. The duration of registered bright sunshine in the week was 11·1 hours. The measured rainfall amounted to 0.49 of an inch.

SEED LIST
(Free on Application).
FEATURES.
Alphabetically arranged.
Best sorts, in heavy type, can be seen at a glance.
Probably the most explicit practical instructions for cultivation ever published.
Many hints and recipes for cooking and serving the various vegetables.
Directions for the storing and forcing of vegetables.
Medicinal qualities of many vegetables and herbs.
Prizes of £5, £3, two of £2, and £1 offered for Photographs of Horticultural Subjects (see page 2 of Catalogue).
THE LIST, containing 93 pages, and a profusion of illustrations, shows (A) **What to Grow**; (B) **How to Grow it**; and (C) **What to Do with it when Grown**; and has been described by an agent on one of the largest estates in England as a BOOK OF REFERENCE.
Another Customer, testifying as to quality, writes: "I should like to add that all the Seeds, &c., purchased from your establishment during the past 14 years have been of the very best quality, and have given great satisfaction."

CARTERS

GREEN PEAS—JUNE TO NOVEMBER.

CARTERS

A correspondence was raised in the Daily Press last Autumn upon the shortness of the season when Green Peas are available, both in gardens and on the market. We now offer the following as representing the best collection selected from 1,024 rows we had under trial last season. It would be difficult for us to give precise dates for putting the seed into the ground, as so much depends upon soil and situation. Successional Sowings may be made any time between these dates, and the last sowing not later than the second week in June.

NAME.	DESCRIPTION.	HEIGHT. ft.	WHEN TO SOW.	EXPECT READY TO PICK.	CARRIAGE FREE. Per Pint.	Per Qrt.

J. R. PEARSON and SONS,

Chilwell Nurseries, NOTTS.

ESTABLISHED 1782.

H. CANNELL & SONS'

Pure Own-Grown Golden Kentish Seeds.

Are the finest the World can Produce.

AS A PROOF, Sir Trevor Lawrence, President, the Council and 30 expert Committeemen of the Royal Horticultural Society, unanimously awarded us the Highest Honour, and also instructed their Secretary, the Rev. Wilks, to say that the Vegetables composing our great exhibit were "WONDERFUL." This unprecedented eulogium speaks for itself.

Send for Ours, the best and most edifying Catalogue ever issued.

Price 1s., post free to customers.

SWANLEY, KENT.

CANNELL'S KING, THE BEST TOMATO.

WE stated and described when we sent out four years ago that our KING was the best in cultivation. All this has proved correct; both for private and market, immensely popular. Whilst others have perished of disease this has flourished; heavy cropper, and certainly the best flavoured. 1s. and 2s. per packet.

SWANLEY, KENT.

STRAWBERRIES & RASPBERRIES

H. CANNELL and SONS have large quantities of all the best field and garden for immediate planting. Send for Catalogue.

SWANLEY, KENT.

CANNELL'S Catalogue of CHRYSANTHEMUMS

WILL be found the best and completest. The whole family beautifully illustrated and described, and our pure country properly grown cuttings and plants have no equal. Post free to coming customers.

SWANLEY, KENT.

VIOLETS AND VIOLAS.

H. CANNELL and SONS have many thousands, healthy country grown plants, in best condition for immediate flowering and planting. New Single Violets are great acquisitions and a constant source of pleasure everywhere. Send for a Catalogue.

AS IMPROVER in a Private Establishment, where cucumbers, vines, tomatos, are grown for market; two years' experience.—MAYNE, Guildford Cottage, Sutton, Surrey.

AS GARDENER (Under, or Single handed); for Kitchen or Pleasure Grounds; age 25; good reference; state wages given, to H. J. BULLOCK, 40, Kingsgate Road, Kilburn N.W.

BARR and SONS have on their Register several competent HEAD GARDENERS. They will be pleased to furnish full particulars on application.—12 and 13, King Street, Covent Garden, London.

CLERK seeks Situation; age 25; nine years' experience with Ledgers, Day Books, Invoicing, &c., in office of large nursery; excellent reference. H. E. C., 1[illegible], Silchester Road, Notting Hill, W.

FOREMAN, General.—Young Man with highest references, seeks engagement as above; thorough knowledge of all branches; left through reduction; abstainer; age 25.—GARDENER, The Firs, River, Dover.

FLORISTS.—YOUNG LADY (18) seeks re-engagement as ASSISTANT; good mounter; excellent references; London preferred.—FLORIST, 150, Harringay Road, South Tottenham.

FOREMAN, or GARDENER, Second.—Age 28; fourteen years' experience in good places; well up in fruit, plants, and decorations; also general work; well recommended.—A., 4, Whitbread Terrace, Hatfield Road, St. Albans.

F. LUNNISS, Esq., Sutton House, Suffolk; highly recommends his late GARDENER to any lady or gentleman requiring a thorough practical man in all branches; decorations, fruits, orchids, &c.; age 32.—H. OGLE, Park Road, Egham, Surrey.

GARDENER (Head Working, or good Single handed); well experienced in all branches; six years' good character; married, age 32.—Address, J. BANKS, 88, Park View Villas, Brighton Road, Reading.

GARDENER (Head Working); age 27; single; able to manage vines, peaches, melons, cucumbers, tomatos, flowers, and kitchen garden.—Write, GARDENER, The Nursery, Romany Road, West Norwood

GARDENER (Head Working); married; age 40; life experience in all branches; stove, greenhouse, plants, vines, peaches, hardy fruit, flowers, and vegetable growing.—H. COLVIN, The Woodlands, Offerton, Stockport, Cheshire.

GARDENER (Head Working, or good Single-handed); vines, peaches, melons, cucumbers, tomatos, chrysanthemums; Inside and Out; age 28; single; good references; no bothy.—Address, W. B. BROGDEN, Junction Road, Burgess Hill, Sussex.

GARDENER (Head Working); where two or more are kept; age 33; married, two children; experience in stove and greenhouse plants, flower and kitchen garden; eight years' good character; disengaged.—HUNT, 9, Turnford Cottages, Broxbourne, Herts.

GARDENER (Head Working); age 25.—Life experience in all branches; 12 months' market work; excellent testimonials; married when suited.—W. BAILEY, Hunton, Kent.

GARDENER (Singlehanded, or where two are kept); age 32; married; life experience in early and late forcing fruit, flowers and vegetables; twelve months' good character.—W. HEWITT, 2, Roxburgh Cottages, Purley.

GARDENER (Second in private establishment where four or more are kept); Inside preferred; age 23; good character; state wages. — W. UNDERWOOD, 52, Ravenswood Road, Balham.

GARDENER (Second, in Private Establishment); Inside preferred. REUBEN DARK, Mereton Gardens, Bideford, would have pleasure in recommending Frederick Pugsley; age 21; three years and eight months' good character.

GARDENER (Under, Inside or Out), age 20; one year in present place, 3½ previous; fair knowledge of inside and out; good character from present and previous employers; gentleman going abroad. — HORACE COLLINS, Canada Lodge, Rogate, near Petersfield.

GARDENER (Under or Single handed). —Wanted by Young Man; age 21; well up in greenhouse, fruit, flowers and kitchen garden; three years' good reference at present situation.—GEORGE GAMMON, Watchbell Street, Rye.

GROOM-GARDENER, age 28; well up in driving, and all branches of the garden; 6½ years' good character.—H. H., care of Mrs. England, 8, Acre Road, Kingston, Surrey.

GROWER, to take Charge. — Age 25; life experience in grapes, peaches, tomatos, cucumbers, roses, chrysanthemums, &c.; good references.—J. C., Ladd's Cotts., Dartford Heath, Dartford.

IMPROVER.—Gardener's Son (aged 20), seeks situation as above; over two years' experience Inside; gentleman's garden preferred; quick, and willing to learn.—H. BENSLEY, Victoria Nurseries, West Humberstone, Leicester.

LORD CARLISLE wishes strongly to recommend his Head Gardener (J. Riddell) to anyone requiring the services of a thoroughly practical, scientific, and energetic gardener of proved ability and integrity; exceptional testimonials and references; leaving through reductions. — Address, J. RIDDELL, Castle Howard Gardens, York.

JOURNEYMAN (First, or Foreman in medium establishment).—Inside; good recommendations from last and previous situations; age 24; abstainer.—S. JORDAN, 31, South Grove, Highgate, London, N.

MANAGER or Foreman.—Over 20 years' experience in growing plants, cut flowers, tomatos, &c., for market and retail; good references.—ROBERTS, Cæsarean Nurseries, Five Oaks, Jersey.

RICHARD SMITH and CO., beg to announce that they are constantly receiving application from Gardeners seeking Situations, and that they will be able to supply any Lady or Gentleman with particulars, &c.—St. John's Nurseries, Worcester.

SHOPMAN, ASSISTANT, requires situation; age 22; eight and a half years' experience in all branches, including two years in a London Wholesale House. —A. F., 63, Roxburgh Street, Kelso.

WANTED, Situation as GARDENER, single-handed or good second; age 26; eight years' good experience, well up in grape and tomato growing; five years excellent character.—H. SKINNER, 3, Bay View, Torquay South Devon.

WANTED Situation as GARDENER, Second, in good establishment; ten years' experience; age 26; past four years at Maristow; last two as Foreman; highly recommended from Maristow and previous places; bothy preferred.—HARRIS, Whitstone Head, near Holsworthy, North Devon.

Situations Vacant.

Advertisements under this heading are charged 2s. 6d. for Four lines (32 words), and 6d. per line of eight words after.

WANTED IMPROVER, Inside, where four are employed in the houses; must be strong and active, and able to take turn on duty; wages, 10s. per week; bothy, milk, and vegetables; state age, experience, &c.—FLEMING, Wexham Park Gardens, Slough, Bucks.

HEAD GARDENER.—Wanted a Man from 35 to 40 (married, without family, and an abstainer preferred), who thoroughly understands the management of vines, orchids, stove and greenhouse plants, lawns, and kitchen garden. —Apply, by letter only, stating qualifications and length of last service, to G. T., Green Hill Park, New Barnet, N.

WANTED, KITCHEN GARDENER; one thoroughly understands his work; age [illegible] to [illegible]; wages £1 a week. — Apply, HEAD GARDENER, The Hermitage, Higham, Kent.

WANTED, good strong Young MAN, about 23; bothy; work Inside and Out; must understand pruning, training, and be Churchman.—R. ALFORD, Hilton Park, Wolverhampton.

NOTICE. AN EMPLOYMENT REGISTRY DEPARTMENT IS CONDUCTED IN CONNEXION WITH THE "GARDENERS' MAGAZINE," AND THE CHARGE FOR AN ADVERTISEMENT INCLUDES A FREE ENTRY ON THE REGISTER FOR ONE MONTH. IF NOT SUITED AT THE END OF THAT TIME, AND IT IS DESIRED THAT A NAME SHOULD REMAIN, IT WILL BE CONTINUED FOR A FURTHER PERIOD UPON RECEIPT OF A REQUEST, IMMEDIATE NOTICE MUST BE GIVEN WHEN AN ENGAGEMENT IS SECURED.

A List of Gardeners on the Register will be supplied upon application to the Publishers if a stamped envelope is forwarded, addressed 148 and 149, Aldersgate Street, London, E.C.

RICHARD SMITH & Co. WORCESTER

Veitch's New Melon— TAUNTON HERO.

First Prize at 11 of the leading Shows in the West of England.
White flesh. Nearly round, lightly netted, golden yellow, grand flavour, free setter.
Packet, 1s 6d. and 2s. 6d.

Veitch's New Cucumber— WESTERN WONDER.

Matchless for Exhibition purposes.
Handsome, splendid deep colour and bloom, very prolific, exquisite flavour. Packet, 1s. 6d.

Veitch's New Cabbage— EARLIEST OF ALL.

Award of Merit R.H.S. 1897. Packet, 1s.

Veitch's New Leek— RENTON'S MONARCH.

Indispensable for Exhibition. Packet, 1s. 6d.

ILLUSTRATED CATALOGUE FREE ON APPLICATION.

ROBERT VEITCH AND SON, EXETER.

VEITCH'S

GENUINE SEEDS.

VEITCH'S MODEL BROCCOLI.

FIRST-CLASS CERTIFICATE, R.H.S.

This splendid variety well merits the high encomiums so frequently expressed in the Gardening Press, being the best and handsomest of all late Broccoli.

PER PACKET, 1S. 6D.

VEITCH'S FAVOURITE FRENCH BEAN.

AWARD OF MERIT, R.H.S.

A most desirable early variety for forcing or general use, producing an immense crop of very long pods of superior quality.

PER PACKET, 1S. 6D.

VEITCH'S CHALLENGER CUCUMBER.

A very prolific variety, growing about 18 to 20 inches in length, evenly proportioned and a deep green colour, highly recommended both for table and exhibition.

PER PACKET, 2S. 6D.

For full description of the above and other CHOICE SEEDS, see CATALOGUE for 1898, forwarded post free on application.

DEATH.

BECKWITH.—On the 16th inst., at Tottenham, George Beckwith, of the Tottenham Nurseries, aged 77 years.

NOTES OF THE WEEK.

AWARDS TO NOVELTIES.

THE report to be presented by the Council of the Royal Horticultural Society to the annual meeting of the Fellows in February is, on the whole, so highly satisfactory, that it is impossible to peruse it without having a strong feeling of admiration for the ability displayed by the Council and officers in the management of the affairs, and experiencing considerable gratification that the society should have attained to so high a degree of prosperity. As will be gathered from the report, of which we give a summary on another page, the whole of the exhibitions and meetings were more or less successful, the work at Chiswick was carried on with the usual activity, there was a large accession of new Fellows, and, as the result of the year's operations, the Council was able to carry forward a substantial amount into this year's accounts. There is, however, one matter to which reference is made by the Council that detracts somewhat from the pleasure experienced in reading the report, and that is the necessity which has again arisen for the Council to urge upon the several committees the importance of checking the tendency to making awards to novelties in too lavish a manner. The committees were in no way wanting in liberality during the past year in the allocation of medals to those who contributed to the exhibitions, for these included fourteen gold medals, and proportionate numbers of medals of less value; but with these we are not specially concerned at the present moment, and speaking in a general way, the medals awarded to exhibitors in the course of the year were well deserved. The cause for the anxiety expressed by the Council, as also for apprehension on our part, is the immense number of awards made to novelties. The table of awards given in the report, shows that fifty-four first-class certificates, three hundred and forty-six awards of merit, and thirty-one botanical certificates were awarded; numbers that fully justify the Council in requesting "the several committees to consider seriously whether there is not a real danger of impairing the value of these distinctions." The question is hardly one for consideration, for the time has arrived when the committees should impose a severe check upon their generous impulses, for already the value of the distinctions conferred by them have been heavily discounted by the prodigality with which they have been distributed. It is, of course, in the highest degree essential that raisers and introducers of new plants, fruits, and vegetables should be encouraged to the fullest possible extent; but it is not less necessary that the interests of the general body of cultivators should be considered, and no award be made to a novelty unless it greatly differs from, or is a marked advance upon existing species or varieties in the same way. It is not sufficient that it should have a merely microscopic difference, or be as good as something else in the same way, and until this fact is recognised by the members generally of the committees, it will be useless to expect any material reduction in the aggregate number of awards made. It is unfortunate that while the Floral Committee has amended its method of procedure in the making of awards to plants that are widely known and generally cultivated, the Orchid Committee should confer first-class certificates upon plants that are in general cultivation. This practice should, in the case of each of the committees, have an effectual check placed upon it by the Council, for it cannot be beneficial to the society, and it certainly reduces the value of the distinctions conferred upon meritorious introductions.

VARIETY IN PLANT HOUSES.

Although it is a quite common occurrence to hear expressions of satisfaction that we have practically escaped from the thraldom of the bedding system, which thirty years ago had undisputed sway in our gardens, the general body of horticulturists are evidently oblivious to the fact that they are rapidly becoming slaves to a practice hardly less detrimental to the full enjoyment of the garden. The craze for scarlet pelargoniums, yellow calceolarias, blue lobelias, and the coloured leafage of coleus and alternantheras that reached its most acute condition during the sixties, had the effect of banishing for a considerable period a large number of our most beautiful hardy plants, and rendering British gardens as uninteresting and unattractive as can possibly be conceived. Happily, during the past fifteen years there has been a decided change for the better in the methods of embellishing the flower gardens. The great masses of gaudily coloured plants that were so painful to the eye and so objectionable to those endowed with artistic preceptions have disappeared, and the beds and borders devoted to plants that at once appeal to those who are able to appreciate beauty of form as well as attractive colouring and by reason of their flowering at different seasons contribute to the attractions of the flower garden from early in the spring until the autumn is well advanced. For this great and beneficial change in the fashion of flower gardening we have good cause for congratulation Had other fashions in horticulture been of late years equally satisfactory the garden prospect would afford unbounded pleasure; but, unhappily, whilst horticulturists have been busily engaged in rooting out one practice that has been so strongly condemned, they have been not less active in establishing another that is hardly less baleful in its influence upon horticulture. Concurrently with a decline in the popularity of summer bedding there has been an enormous increase in the use of plants and cut flowers in decorations, and the trend of public taste at the present time in matters relating to the garden is such as to justify considerable anxiety on the part of those who, and properly so, regard some diversity in the plants grown under glass as essential to the full enjoyment of the several plant houses. Nearly everything is being made subservient to the decorative aspects of plant culture, and the value of a new tender-flowering or ornamental-leaved plant is usually estimated not so much by its intrinsic beauty and interest as by its utility in the production of a bright display of colour for the decoration of indoor apartments. In consequence of this change in fashion, considerable numbers of beautiful orchids, ferns, and greenhouse and stove plants have no place in the majority of gardens, and the plant houses are shorn of their interest, which to our mind constitutes one of their great charms. It has become quite usual to find orchid houses wholly devoted to a few species and their varieties; indoor ferneries almost exclusively given up to free-growing adiantums and pteris, and the greenhouse and stove chiefly employed in the production of plants specially adapted for the production of supplies of cut flowers or the decoration of the dinner-table or drawing-room. We have consistently advocated the cultivation of plants adapted for the adornment of the home, but in all cases as supplementary to the general collection, and not, as is becoming so general, to the exclusion of all others. It is not desirable that an attempt should be made in private gardens to emulate Kew or Glasnevin, but the collections should be sufficiently comprehensive to adequately represent the vegetation of temperate and tropical regions, for only where this is done can the garden properly fulfil its mission, and give unbounded interest and pleasure to those who come within its influence.

PLANT SLEEP.

The ebb and flow of vitality in all living organisms is a very curious phenomenon. In the vast majority of cases it synchronises either with the appearance or disappearance of the sun, as with man and most animals, with whom the season of darkness is the season of sleep; with the lowering of temperature in the winter time, as with most plants, whose sleep is annual; or with periods of alternate drought and wet, as in the tropics, where dormancy is enforced by lack of moisture. Nature, however, with her usual disregard of hard and fast lines, has her exceptions in all these cases; hence we have beasts and birds and insects which seek their prey under cover of the night, and sleep in the daytime; flowers, like the evening primrose tribe (*Œnothera*), which open their petals to the setting sun to woo the nightingale's kisses, and plants of the most succulent character, the ice plant to wit, which, defiant of heat and drought, flourish despite them. Many plants, too, take nightly rest like man himself, and, like the woodsorrel (*Oxalis*), fold up their leaflets when the sun goes down and sleep till dawn. Then, too, our familiar garden plants belong to two categories, the one the children of the summer sun, both annuals and perennials, the other the firstlings of the spring or, like the Christmas roses, pale offsprings of King Winter himself; and if we take a stroll round our gardens now, and use our eyes we shall see a thousand evidences of life, though, to a casual glance, the sleep is general. All the spring bulbs—the tulips, hyacinths, scillas, crocuses—are on the move, and every here and there their sharply-pointed spikes can be seen pushing their way to the light. The Spanish iris is up in spiky profusion several inches, and the first wedges of the daffodils show here and there with promise of the golden blooms to come. Not only the bulbs, however, are busy preparing for the fray ; in the hearts of the pæony the red buds are swelling ; the primulas and auriculas are profiting by the mild season to show their sleep is half a makebelieve ; megaseas globular sheaths, in which the blossom lies, show fresh, clean surfaces as that blossom swells. The hepaticas in their hearts show nascent hairy buds, and nine perennials out of ten are plainly on the move. Even the ferns in some species are fattening up their crowns, and show new growth in their centres, though we may be certain that no blandishments of the weather will induce them to rise for two or three months to come. This brings us to the curious fact that few plants, under natural conditions, are premature in their full awakening. All this that we have noted is a slow preparation, but these visible spikes and nascent growths are either hard-frost proof or developed under protecting débris, so that, should a cold snap occur, no harm is done to the blossom hid deep within, which will remain snugly ensconced there until the proper period arrives for their full development. It is our highly-cultivated plants which lose their instincts as it were, or cling maybe too long to inherited habits developed in other climates. But, truth to tell, the English spring is a tricksy season, ruled seemingly by Puck himself, and it must be indeed a wise plant which never gets caught, not "napping" indeed, but wide awake when it should not be.

American Apple Grub.—There is some reason to fear that our already much-infested apple trees have acquired yet another pest from America. Many of the apples from a Devonshire orchard were observed to be perforated by some insect, and the injury was attributed to the familiar "codlin moth," Carpocapsa pomonella. Something unusual in the appearance of the injured fruit, however, induced a member of the Royal Agricultural Society to send a specimens to the Zoologist. Unfortunately this was not until October 26, when the fruit had been deserted by the insect, and there was no clue to the depredator beyond the appearance of the injury. Clearly this was not the work of the codlin moth, but of some smaller insect present in considerable numbers. Precisely similar injury is, however, wrought in the Northern States of America by the larva of a fly scientifically known as Trypeta pomonella, an insect somewhat closely allied to our "celery fly." The absence of any pest hitherto known in England capable of causing this particular injury, and the exact correspondence between the damaged apples from Devonshire and American apples attacked by the "apple-grub," leave very little room for doubt that this destructive pest has obtained a footing in our country. In the case of apples infested by the "apple grub" instead of the one or two large tunnels of the codlin caterpillar, the fruit is riddled with small borings, and, at a later stage, there are numerous surface holes at which the grubs have escaped to pupate in the ground. There are two possibilities which may be suggested. The pest may have been present among us for some years, but its injury attributed to the codlin moth. On the other hand this may be in reality its first appearance, but it by no means follows that our climate will allow it to survive the winter and continue its depredations next spring. Other pests have made a similarly sudden appearance and flourished for a season, but have been unable to maintain their ground. The best means of checking the pest is the gathering up of the injured apples as soon as they fall from the trees, and before the grubs have time to enter the ground to pupate ; and as this measure is equally effective against the codlin moth, it cannot be too strongly insisted upon.

Honours for Chrysanthemum Growers.—Among the French New Year's honours to horticulture, we are much pleased to find that our old friend, M. H. Fatzer, the well-known cultivator of large-flowering chrysanthemums, grapes, &c., has been appointed a chevalier of the Mérite Agricole by the French Government, another testimony to the impartiality with which distinguished service in horticulture is recognised by the French, for M. Fatzer is not a French subject but a native of Switzerland. M. de Reydellet, the seedling raiser, has also received the same distinction.

Annuals and Biennials for Decorative Purposes.—N. N. Sherwood, Esq., Master of the Worshipful Company of Gardeners, having signified his intention of giving R.H.S. a silver cup annually, of the value of £10 10s., and having left to the Council the decision as to what it shall be given for, it has been decided to award it this year to the exhibitor who shall obtain the highest total number of marks at the meetings in June, July, August, and September 6, for collections illustrating the suitability of annuals and biennials as cut flowers for decorative purposes. Exhibitors may exhibit at any one or more or at all of the meetings during the months named. Marks will be given at each meeting, and the total announced after September 6. The contents of each tube must consist of one variety only, but in addition to the flowers shown in tubes, an exhibitor may set up at each or any of the meetings not more than three plain glass vases containing an assortment of varieties and kinds arranged for effect—all stalks touching the water or sand. The vases must be provided by the exhibitor, and must not exceed six inches in diameter, and may be filled with water or with wet sand at exhibitor's pleasure, always remembering that the clearness of both water and glass is a distinct point of advantage in decorative vases.

The New Open Space at Islington, a part of the Cattle Market area, was purchased recently for the sum of £8,000. The vestry of the parish of Islington has now voted £10,500 for the purpose of laying out the space as a recreation ground and garden. A large covered space for the use of children on rainy days, and also a museum, are contemplated. Such a garden as this will be a great boon to the population of a very congested area.

Weather Influences on Farm and Garden Crops.—At the annual meeting of the Royal Meteorological Society, the President, Mr. Edward Mawley, gave an address on "Weather Influences on Farm and Garden Crops," in which he pointed out the intimate connection between meteorology, agriculture, and horticulture. He explained the special characteristics of the climate of the British Isles as regards temperature, rainfall, &c. Of all the influences brought to bear on vegetable life by the atmosphere, he considered temperature to be the most powerful and far-reaching, and only second to this came rainfall. The leading effects of snow, wind, and sunshine, as well as of prolonged droughts, severe frosts, and persistent rains, were also described. He then dealt with the influence of different important changes on such farm crops as wheat, roots, grass, &c., as well as on fruit trees, vegetables, and flowering plants in the garden. In his concluding remarks he called attention to the great want of experimental farms in conjunction with meteorological stations being estsblished in this and other countries in Europe. For it was only by the examination of meteorological observations, together with weekly records of the extent and growth made by our leading crops, that the close connexion existing between weather changes and their influences on such crops could be clearly traced.

Veitch Memorial Trust.—At a meeting of the trustees, held on January 19, Dr. Maxwell Masters in the chair, it was unanimously resolved that medals for objects to be hereafter determined should be allotted for the present year, at exhibitions to be held at Bristol, Leicester, and Cardiff respectively. A sum of £20 was voted to the trustees of the Lindley Library towards the preparation of the catalogue now in progress. Medals were also allotted to M. Marliac, in recognition of his success as a hybridiser ; to M. Ed. André, of Paris ; and to M. le Comte de Kerchove, of Ghent, President of the Royal Agricultural and Botanical Society of Ghent, for their respective services to horticulture.

The Hamburg International Horticultural Exhibition that was such a prominent feature in the horticultural world during 1897, was brought to a successful close last October. The accounts have been now closed, and it appears that there is a profit of 300,000 marks (about £15,000). A material portion of the income was derived from the rental of dining halls, restaurants, and sale of privileges ; season tickets realised 810,000 marks, and daily tickets 770,000 marks.

Watercress Culture.—The remarkable increase that has during the past two decades taken place in the consumption of the most wholesome of our salad plants should obtain a large share of attention for the paper which Mr. W. W. Glenny has contributed to the Royal Agricultural Society's Journal on the history and cultivation of watercress. Watercress is an indigenous cruciferous plant, growing freely in wet and especially in shallow places, and has probably been used as a salad plant in this country from time well-nigh immemorial, supplies being obtained from neighbouring brooks and streams. It has long been cultivated in some parts of the Continent, notably in the neighbourhood of Erfurt, but it was not until the beginning of the present century that the watercress was included amongst the cultivated plants of Great Britain. It appears that in 1808 William Bradbery first started the cultivation of watercress at Springhead, about one and a half miles from Northfleet, Kent, and close to the secluded village of Swanscombe ; and in a comparatively short period the cresses from these beds were highly esteemed, and the cultivation of watercress at Springhead has been continued until the present time. Mr. Sylvester carries on the business founded by Bradbery in 1808, and the cresses grow as vigorously as at first, owing in a large measure to the plentiful supply of water from the chalk. The cultivation of watercress is carried out on a large scale at Mapledurwell, Overton, and Echinswell in Hampshire, at Kintbury in Berkshire, at Abinger Hammer near Dorking, at Arundel in Sussex, at Rickmansworth and other parts of Hertfordshire. Ten or eleven years after commencing the cultivation of watercress at Springhead, Bradbery migrated to West Hyde, near Rickmansworth, and established watercress culture on scientific lines, and it has been continued ever since by himself and his descendants. On February 19, 1822, Bradbery was presented by the Royal Horticultural Society with their silver medal in recognition of the public services he had rendered in founding the industry ; and this medal is still in the possession of his son. While Bradbery greatly appreciated the honour conferred upon him, it is conjectured that it cost him at least £1,000, as the presentation directed general attention to the industry, and a considerable number of persons engaged in watercress culture, with the result that there was a reduction in the value of the produce. With regard to the area under watercress culture, Mr. Glenny states that "on the Colne, between North Mimms and Staines, there are about twenty-two acres ; on the river Gade, between Great Gaddesden and Rickmansworth, about forty-two acres ; on the river Bulbarne, from Dudswell to Hemel Hampstead, about forty-one acres ; on the Mibaume Stream, from Great Missenden to Denham, about seven acres ; on the river Chess, between Chesham and Rickmansworth, about sixteen acres ; on the Aldenbaume, between Fulmer and Ives, about four acres ; on the river Ver, from Marget to Watford, about five acres ; on the Tillingbourne, between Abinger Hammer and Chilworth, about fifty-one acres."

Edible Fungi on Beech Trees.—A box of fungi was sent by Lady Cave, Clere Hall, Downend, near Bristol, to the Scientific Committee of the R.H.S., but, as that body was unable to identify the specimens, they were forwarded to Kew. The report from Kew stated that the species was Pleurotus ostreatus *Jacq.*, one of the best and safest of edible fungi. The specimens were taken from a very old beech in the gardens of Clere Hall. They were growing on the wood about twelve feet from the ground.

The Reading Gardeners' Association held a tea and smoking concert in the Abbey Hall on the 17th inst., when about a hundred members came together and spent an enjoyable evening. Mr. C. B. Stevens, president of the society, occupied the chair, and the musical programme was carried out by members and a few friends.

Royal Gardeners' Orphan Fund.—We have much pleasure in announcing that C. E. Keyser, Esq., of Aldermaston Court, Reading, late of Stanmore, will preside at the festival dinner of the Royal Gardeners' Orphan Fund, which is to be held at the Hotel Metropole on April 20.

R.H.S. Lectures.—The lectures to be given at the afternoon meetings of the Royal Horticultural Society during the current year are as follows: The Rev. George Henslow, V.M.H., who has been appointed Professor of Botany to the society, on "Some of the Plants Exhibited," March 8, May 10, June 28, October 11, November 8, and December 13; Mr. J. J. Willis, "Soils," March 22; Mr. J. Enock, "Blight and Blessing," April 12; Mr. F. W. Burbidge, V.M.H., "Sweet-scented Leaves *versus* Fragrant Flowers," April 26; Mr. J. O'Brien, V.M.H., "Hybrid Orchids," June 14; Mr. N. N. Sherwood, V.M.H., "Edible Peas," July 12; Mr. A. B. Freeman-Mitford, C.B., "Economic Uses of Bamboos," July 28; Mons. Latour Marliac, "Water Lilies," August 9; Mons. Henri de Vilmorin, "Perpetual Strawberries," August 23; Mr. T. W. Birkenshaw, "The Disa," September 6; Mr. W. Roupell, "Fruit Growing in Suburban Gardens, September 20; Mr. George Gordon, V.M.H., "Experimental Horticulture," October 26; and Mr. A. D. Hall, Principal of the South-Eastern Agricultural College, Wye, "Artificial Manures in the Garden," November 22. The afternoon meetings will, as usual, commence at three o'clock.

The Gardeners' Royal Benevolent Institution is being steadily built up in a most substantial manner, for its invested funds are now bringing in an annual income of over £850. It will be of interest to many, especially in view of the annual meeting and election of pensioners, in progress as we go to press, to know how and what are the funds invested. They are as follows: Two and Three-quarters per Cent. Consolidated Stock, £5,000; India Three per Cent. Stock, £2,664 19s. 10d.; London and North-Western Railway Three per Cent. Debenture Stock (cost £5,363 8s. 6d.), £5,000; Midland Railway Three per Cent. Debenture Stock (cost £5,865 4s. 9d.), £5,414 2s.; Great Indian Peninsula Railway Five per Cent. Guaranteed Stock (cost £5,062 19s. 9d.), £3,000; Manchester Corporation Three per Cent. Stock (cost £4,133 6s.), £4,054 12s. 9d.; Midland Railway Three per Cent. Debenture Stock (cost £500), Mr. and Mrs. Harry J. Veitch's Special Fund, £479 10s. 4d.; Liverpool Corporation Three-and-a-Half per Cent. Stock (Wm. Thomson Memorial Fund), (cost £257 3s. 5d.), £195 14s.; Cardiff Corporation Three per Cent. Stock (cost £535 1s.), £500; and Liverpool Corporation Three-and-a-Half per Cent. Stock (cost £409 10s.), £312 19s. 9d. The new investments are: (J. M. Thomson legacy) India Three-and-a-Half per Cent. (cost £457 5s. 11d.), £389 10s. 9d.; and Victorian Era Fund, Great Western Guaranteed Five per Cent. (cost £4,075), £2,128.

Technical Education.—At the close of an interesting lecture on the subject of edible stemmed plants for food, delivered by Mr. A. Dean, one of the horticultural lecturers to the Surrey County Council, before the members of the Chiswick Gardeners' Mutual Improvement Society, on the 6th inst., there being a large attendance, one member referred to the energetic action of the Surrey County Council in providing able lecturers for that county, whilst the Middlesex County Council, so far at least as horticulture is concerned, did nothing. Mr. Dean, in replying, said it was a grave matter that the large sum paid to the Middlesex County Council by the State for essentially technical education purposes, should not be fully applied to that object. It was so in almost every other county in the kingdom, only a few councils failing to realise the importance of secondary education. It was particularly noticeable in Middlesex, because that county was probably more than any other, for its area, dependent for its prosperity on gardening, especially for market purposes. He suggested that the committee of that society should send to the county council a copy of their present season's lecture-list, which was an admirable one, and at the same time ask for a grant from the technical education subsidy in aid of their objects. It would be a good thing did every similar society in Middlesex make similar demands on the county council, as that would help to instruct the members as to their duty in relation to technical education. It would equally be well did gardeners' mutual improvement associations all over the kingdom make similar requests from their respective county councils. In the course of the discussion a member drew attention to the recent award of scholarships by the London County Council, to be utilised at the Regent's Park Botanic Gardens. This evoked some criticism, as these gardens, it was pointed out, could not instruct in complete practical gardening, but only in that of a decorative character. In returning thanks for a cordial vote given for the lecture, Mr. Dean strongly urged the young members present to sit as candidates at the forthcoming examination of the Royal Horticultural Society in April next.

Attraction of Flowers for Insects.—A summary of Professor Plateau's views, after numerous experiments, with respect to the conditions which induce insects to visit flowers, is given in *Nature*. The professor states that in seeking for pollen or nectar, insects are guided only to a subsidiary extent by the sense of sight. They continue to visit scented flowers after the coloured parts have been almost entirely removed. When flowers of the same species vary in colour, they exhibit neither preference nor antipathy for one colour over another. Inconspicuous flowers hidden among foliage attract large numbers of insects. Artificial flowers made of paper or calico, even when brightly coloured and closely resembling real flowers, are not visited by insects; but they are when made of green leaves which have a vegetable scent. If flowers which have little or no nectar, and which are therefore habitually neglected by insects, are smeared with honey, insects are attracted in large numbers. On the other hand, if the nectary is removed from flowers habitually visited, their visits cease at once. M. Plateau has paid especial attention to entomophilous flowers, and finds that their exemption from the visits of insects is due mainly to their not providing them with honey. From all these facts M. Plateau draws the conclusion that the guiding sense to insects in visiting flowers must be chiefly the sense of smell.

ROYAL HORTICULTURAL SOCIETY.

Summary of Annual Report.

THE Council of the Royal Horticultural Society state in their report to be presented to the annual general meeting of Fellows to be held at the society's offices, 117, Victoria Street, Westminster, on Tuesday February 8, that the year 1897 will long be remembered as the Diamond Jubilee year of Her Most Gracious Majesty, patron of the society, remembered too, for the innumerable projects set on foot in celebration of the event. In the report for 1896 the Council announced that they had no intention of adding to the number of projects by starting any ambitious horticultural celebrations, which would lay any strain upon the resources of individual Fellows. They stated that they proposed to establish a medal of honour in horticulture, and they had obtained the sanction of Her Majesty to call it the Victoria medal. This proposal has been duly carried out; the medal has been prepared, and conferred on sixty recipients distinguished in various ways in our art and science; and it it believed to be the only medal associated with Her Majesty's Diamond Jubilee, with the exception of the one founded by herself. It is moreover the only horticultural distinction in this country that is conferred for personal merit only, and is entirely unconnected with prize-winning. By their action in this matter the Council consider they have commemorated Her Gracious Majesty's Jubilee in a becoming and enduring manner: in a manner absolutely distinct from all celebrations; in a manner that lays no tax upon the Fellows of the society; in a manner distinctly to the advantage and encouragement of horticultural skill and effort; and lastly, in a manner which will carry down to all future generations of horticulturists, the memory of Queen Victoria's long and happy reign.

Under the head of ordinary expenditure at Chiswick £1,850 has been spent on the general work and maintenance of the gardens. Amongst other work. House No. 11 has been partially, and No. 10 entirely rebuilt, whilst No. 5, devoted to peaches, has been raised in height and a new roof put on. All this work has been done by the society's own staff of men. The receipts by sale of surplus produce amount to £357, making the net ordinary cost of the gardens £1,493.

At Westminster, twenty fruit and floral meetings have been held in the Drill Hall, James Street, Victoria Street, and fifteen committee meetings have been held at Chiswick, besides the larger shows in the Temple Gardens on May 26, 27, and 28; and at the Crystal Palace on September 30, October 1 and 2. Lectures have been delivered at seventeen of the meetings, exclusive of those given at the Crystal Palace. The number of awards granted by the Council, on the recommendation of the various committees, has been as follows: Gold Medal, 14; Silver-gilt Flora, 55; Silver-gilt Knightian, 18; Silver-gilt Banksian, 35; Silver Flora, 132; Silver Knightian, 50; Silver Banksian, 153; Bronze Flora, 16; Bronze Knightian, 4; Bronze Banksian, 54; First Class Certificate, 54; Award of Merit, 346; Botanical Certificate, 31; Cultural Commendation, 46; total 1,008.

The Council must again express their opinion that there still appears to be a tendency to multiply unduly the awards recommended, and they earnestly request the several committees to consider seriously whether there is not a real danger of impairing the value of these distinctions by such increase of their number; and whether it would not be possible, as well as politic, to be somewhat less generous in the recommendation of awards during the ensuing year. This is a question which the Council cannot but regard with solicitude, and they hope that every member of the committees will consider that he has a real individual responsibility for the welfare of the society in this matter.

On Wednesday, July 14, the Council invited all the members of the several committees to lunch with them at Chiswick, and to examine the Gardens. After the luncheon an address was delivered by Dr. Maxwell Masters, F.R.S., on the possibility of an extended usefulness of the Gardens.

The Council desire to draw the attention of all Fellows of the society to the more extended use which the Scientific Committee might be to them if they availed themselves more freely of their privileges in submitting instances of diseases of, or injuries to plants, caused by insects or otherwise. The Scientific Committee is composed of gentlemen qualified to give the best advice on all such subjects, either in respect to the prevention or cure of disease. The committee is also glad to receive specimens of any subjects of horticultural or botanical interest. The Council wish to express their thanks to the Director of the Royal Gardens, Kew, for allowing them to consult Mr. Massee, F.L.S., on the fungoid diseases, &c., brought before the Scientific Committee, and to that gentleman for his readiness in giving them the advantage of his knowledge and advice.

That Fellows, whether near or at a distance, may derive as much benefit as possible from their connection with the society, the Council have recently appointed Dr. J. Augustus Voelcker, M.A., consulting chemist to the society, and have entered into an arrangement with him whereby all Fellows who are amateurs or *bona fide* gardeners, may obtain at very small cost analyses of manures, soils, &c., or advice as to what description of chemical manure will be most suitable and profitable for application to any particular soil. The Council wish to draw particular attention to two points, viz.:—

(i.) That Fellows desiring an analysis must follow explicitly and exactly the directions laid down in the Book of Arrangements, 1898; and

(ii.) That Fellows who are in any way commercially interested in any artificial manure trade or horticultural business cannot claim Dr. Voelcker's assistance as Fellows, but if they wish to consult him must do so in the ordinary way of business.

The society's great show held (by the continued kindness of the Treasurer and Benchers) in the Inner Temple Gardens, was as successful as ever, and it is a matter of satisfaction to the Council to find that this meeting is now universally acknowledged to be the leading horticultural exhibition of this country. The best thanks of the society are due to all who kindly brought their plants for exhibition, or otherwise contributed to the success of this show. The exhibition of British-grown fruit held by the society at the Crystal Palace on September 30, October 1 and 2, was, considering the season, eminently satisfactory. A certain amount of dissatisfaction has arisen from the fact that whereas classes have been provided specially for amateurs and gentlemen's gardeners, and also for nurserymen, there have been no classes in which growers for market could properly exhibit. This will in future be avoided by the addition of a division for growers for market only.

As an object-lesson in British fruit cultivation this annual show stands unrivalled, and is of national importance. The Council invite Fellows and their friends to support it, for it cannot be too widely known that the continuance of the show is absolutely dependent on at least £100 being raised by subscription each year towards the Prize Fund. The show involves the society in a very large expenditure without the possibility of any return. The Council have therefore established the rule that they will not continue it unless sufficient interest in it is taken by Fellows and their friends to raise £100 towards the Prize Fund. Subscriptions for this purpose should be at once sent to the Secretary, 117, Victoria Street, Westminster, and if the list prove satisfactory the schedule will be issued in April, and the show will be held on September 29, 30 and October 1, 1898.

A deputation was sent by the Council, at the invitation of the local authorities, to attend the great horticultural gathering at Shrewsbury in August. The Council gladly embraces this opportunity of congratulating Shrewsbury on the magnificent display of horticultural skill and enterprise made at their show, and of recording the very great pleasure which this visit gave them, and their appreciation of the great courtesy and hospitality with which they were received. An invitation has been received and accepted for a similar deputation to visit a show, to be held at Newcastle-on-Tyne, on July 13, 14, and 15, 1898, by the Botanical and Horticultural Society of Northumberland, Durham, and Newcastle-on-Tyne.

The *Journal* of the society has been continued so as to enable Fellows at a distance to enter more fully into, and reap the benefits of the study and work of those actively engaged at head-quarters. Vol. xx., part 3, and parts 1 and 2 of Vol. xxi., were issued during the year, and vol. xxi., part 3, will be ready in March.

The Council have heard with much pleasure that Mr. G. W. Burrows, a member of the court of the Worshipful Company of Gardeners, has most kindly offered, in connection with the society's 1898 examination, a scholarship of £25 a year for two years; full particulars of which will be found in the society's arrangements for 1898, lately issued to all Fellows. Another similar scholarship has been promised for 1899 by the Right Hon. the Lord Amherst of Hackney, through the same worshipful company.

Acting in conjunction with the Lindley trustees, the Council have devoted considerable attention to the library, All serial publications have been kept up to date, a large number of valuable volumes have been bound, and the following new books, amongst others, added to the library, viz.: "The Flower Garden of Ornamental Bulbous Plants," Labouret's "Monographie de la famille des Cactées," Sweet's "Florist's Guide," "The Floral Cabinet and Magazine of Exotic Botany," "The Yew Trees of Great Britain and Ireland," &c., &c.

The hearty thanks of the society are due to all the members of the standing committees, viz., the Scientific, the Fruit and Vegetable, the Floral, the Orchid, and the Narcissus Committees, for the kind and patient attention which they have severally given to their departments; to Mr. N. N. Sherwood and Mr. C. J. Grahame; to all those who, either at home or abroad, have so kindly presented books to the library, or plants or seeds to the gardens; and to all who have so kindly contributed, either by the exhibition of plants, fruits, flowers, or vegetables, or by the reading of papers, to the success of the fortnightly meetings in the Drill Hall. They are glad to find by the increased and increasing number of visitors that the society's fortnightly meetings are becoming better appreciated by the Fellows and public in general. In their judgment these shows, which take place at short intervals throughout the year, furnish horticultural displays and teach horticultural lessons which cannot be obtained elsewhere in the kingdom.

The Council are glad to be able to announce that they have appointed the Rev. George Henslow, M.A., V.M.H., F.L.S., &c., to be Professor of Botany to the society, and Professor Henslow has kindly undertaken to give addresses at a number of the 1898 meetings, drawing attention to interesting points connected with some of the plants, &c., exhibited. The Council are confident that these "demonstrations" will be greatly appreciated by the Fellows.

A scheme for the affiliation of local horticultural societies was put forward in 1890, and ninety-one local societies have availed themselves of it. The Council express the hope that Fellows will promote the affiliation of local horticultural and cottage garden societies in their own immediate neighbourhood.

The Council have the sad duty of recording the death of fifty-three Fellows during the year, and among them they regret to find the names of Dr. Robert Hogg, one of the most staunch and energetic supporters of the society, and the leading authority in fruit nomenclature, James Bateman, the pioneer of orchid culture in this country, and author of the "Orchidaceæ of Mexico and Guatemala," Colonel Trevor-Clarke, W. G. Head, Robert Owen, James Cocker, George Rennie, and Francis Fell. The following table will show the society's progress in regard to numerical strength during the past year:—Deaths in 1897, 53, resulting in a loss of income of £68 5s.; resignations, 50, resulting in a loss of income of £66 3s. The total loss of Fellows was 103, and of income £134 8s. Fellows elected and societies received into affiliation 1897, 428, representing an annual income of £551 15s. 6d.; deduct loss, £134 8s.; net increase in income, £417 7s. 6d.; new Fellows, &c., 428; deduct resignations and deaths, 103; numerical increase, 325.

From the annual revenue and expenditure account, we learn that the expenditure was as follows: To establishment expenses, £1,960 14s. 3d.; Victoria medal of honour, £174 14s. 3d.; shows and meetings, £968 17s. 8d.; prizes and medals, £525 14s.; Chiswick Gardens, £1,851 6s. 1d.; balance, £822 7s. 4d.; total, £6,303 13s. 7d.

The income was as follows: By annual subscriptions, £3,824 12s. 6d.; shows and meetings, £1,528 11s. 5d.; advertisements in journal, £323 0s. 4d.; sale of journal, £36 9s. 9d.; miscellaneous receipts, £40 8s. 6d.; dividends, £117 9s.; interest on deposit, £15 6s. 4d.; prizes and medals, £60 12s. 6d.; Chiswick Gardens, £357 3s. 3d.; total, £6,303 13s. 7d.

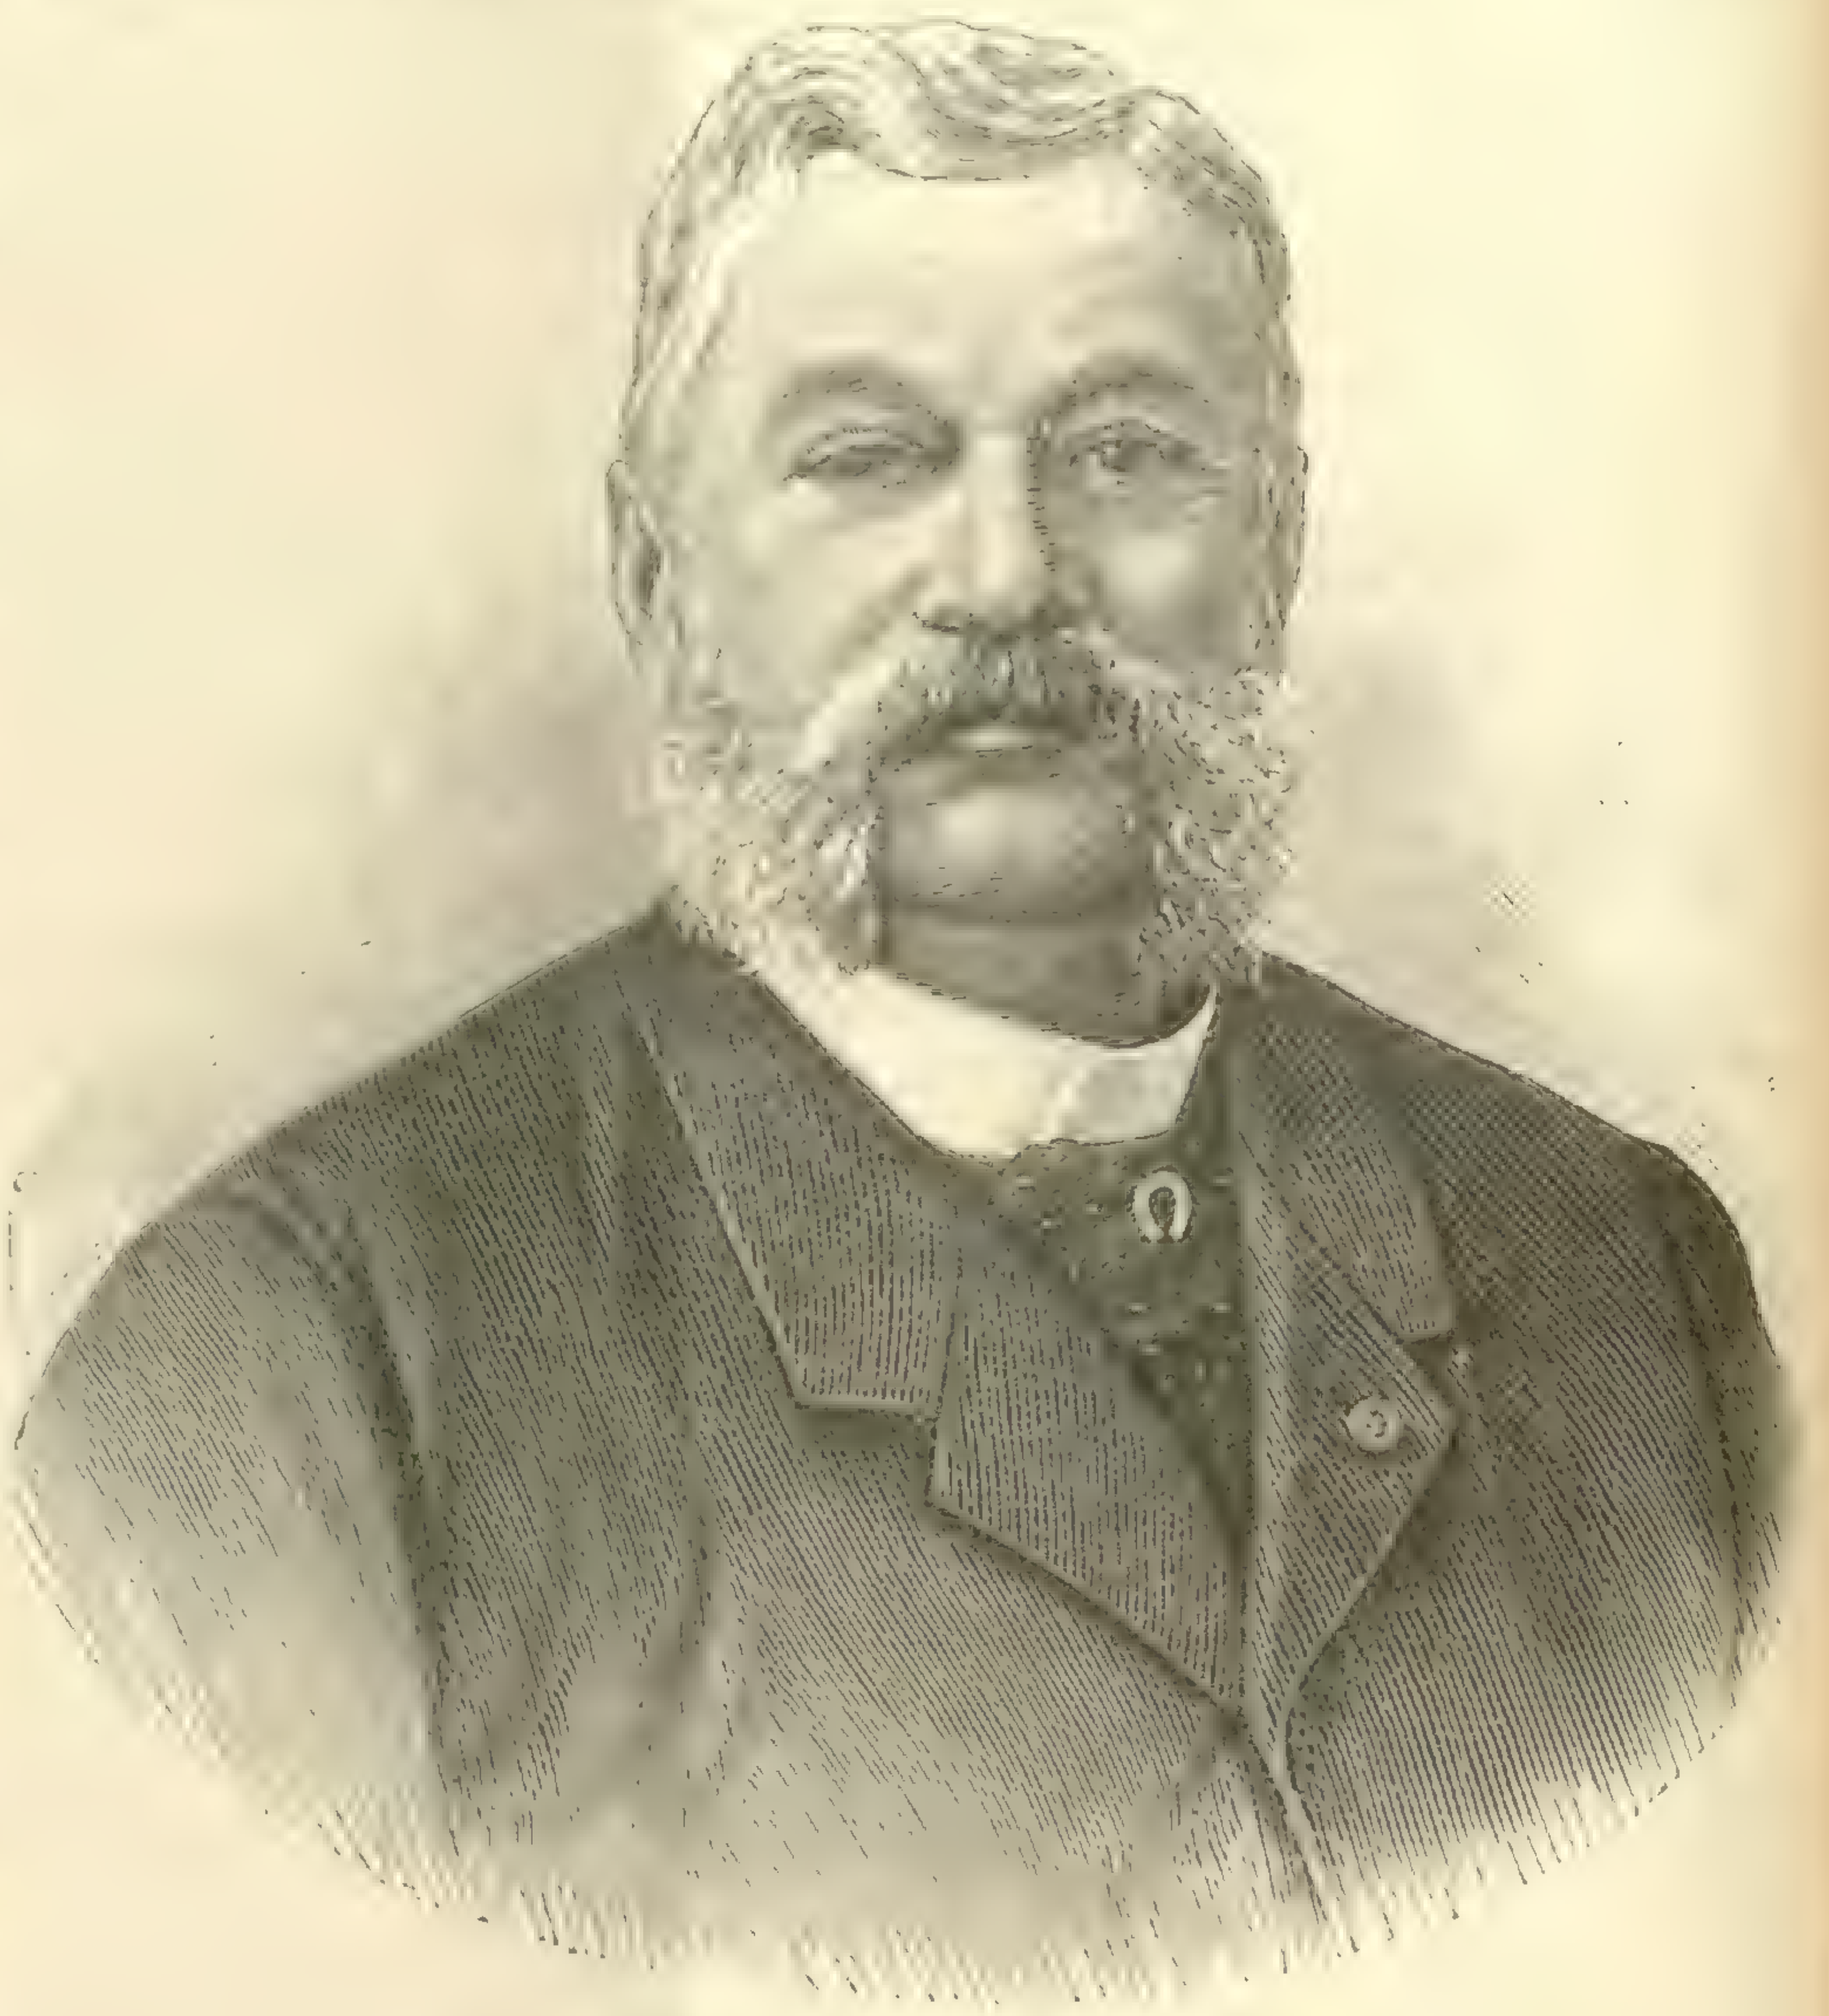
The balance-sheet shows that the society had at the end of the financial year the sum of £4,218 7s. 3d. invested, and of £963 7s. 9d. in cash, on current and deposit accounts and in hand.

The usual changes in the constitution of the members of council will be made. The three retiring members are: Mr. Norman C. Cookson, Mr. James Douglas, and Mr. T. Gabriel; and the Fellows recommended to fill the vacancies are: Sir F. Wigan, Bart., Mr. J. Gurney Fowler, and Mr. James Hudson.

Mushroom Culture on a Large Scale is carried on in Edinburgh in a disused railway tunnel that lies sixty feet below the streets. This tunnel is three thousand feet long, and here Messrs. Robert and John Paton have for the past ten years produced immense quantities of the common edible fungus until they now practically control the market. It is said that when in full operation about one thousand tons of manure and one thousand bushels of spawn are used per year. There are about eight hundred mushroom beds in all, and the great success in every case is largely due to the fact that in this tunnel the temperature varies only to the extent of ten degrees from summer to winter. In cases of prolonged severe frost a fire is lighted in the mouth of the tunnel. With the exception of a single set of rails along the centre of the tunnel all the floor space is covered with mushroom beds, chiefly twelve feet by three feet in size. Cleanliness is practised more than anyone might expect, for the walls and roofs are periodically whitewashed, and it is said that the cost on each occasion reaches £300. The output is, of course, enormous, the highest for one month being 5,000 lb., whereas ten years ago we mostly used French mushrooms; now the imported produce is but a small part of the total supply.

THE LATE M. JEAN LINDEN.

THE remains of this distinguished explorer and horticulturist were laid to rest within the precincts of the church of St. Josse-ten-Noode in the forenoon of Friday the 14th inst., in the presence of a large number of private friends and the representatives of botany, horticulture, literature, and the fine arts. The Grand Duke of Luxembourg was represented by Comte d'Ansembourg, and among those present, who are closely identified with botany and horticulture, were: M. Ferdinand Kegeljan, president of the Horticultural Society of Namur; Dr. E. Rodigas, director of the Ghent School of Horticulture; M. Lubbers, secretary of the Royal Floral Society; M. Louis Van Houtte and M. Romain de Smet, delegates of the Syndicate of Belgian Horticulturists; M. Gillekens, M. Jean Van Lagenhove, Ghent; M. de Lombaerd, M. Ernest Delaruye, delegate of the Cercle Van Houtte; M. Crepin, M. Jaoris, M. Madoú, Dr. Capart, Marquis de Wavrin, M. Peteers, M. de Langhe, M. Vervaen, M. Stepman, M. de Messemaeker, M. de Craen, and M. Longe. As a commander of the Order of Leopold, M. Linden was accorded military honours by detachments of grenadiers and carbineers.



THE LATE M. JEAN LINDEN.

The chapel presented an imposing appearance, for it was gracefully decorated by fine palms, emblems of immortality. Crowns, sheaves, and crosses of natural flowers were abundant, and the immense number of orchids sent showed that a wide circle regarded Mons. Jean Linden as the father of orchid introduction. The members of the family, L'Orchidéenne, L'Horticulture Internationale employés, M. M. Wincqz, du Trien de Terdonck, Marquis de Wargny, Joris and Stepman, were among the large number of those who contributed handsome crowns of flowers. Among those gathered to do honours to the great departed, three made brief reference to his ability and character. These were M. Kegeljan, who spoke in the name of L'Orchidéenne; M. Rodigas, in the name of the Ghent School of Horticulture; and a delegate from the Union of Old Students of the Brussels University. The universal esteem in which the late Mons. Linden was held was once again fully demonstrated at his funeral.

ANCIENT SOCIETY OF YORK FLORISTS.

THE annual meeting was held on the 12th inst. at the Agricultural Club Chambers, Mr. J. E. Wilkinson presiding over a large attendance. The report presented by Mr. J. Lazenby, the secretary, showed that the year's work had been very satisfactory. The five usual minor shows were held, and the April, July, and September shows were excellent. Hyacinths, auriculas, roses, dahlias, asters, &c., were largely shown, and were above average in quality. After describing the general excellence of the floral display, the fruit, &c., the report expressed obligation to donors of special prizes. Financially, it was satisfactory to note that at the close of the year there was a balance in hand of £180 11s. 11d., as against £177 17s. 1d. last year. There was a decrease in subscriptions from members. Loss by death and removals from the city had unusually affected the society, but recently there had been accessions which had more than balanced the loss. Thanks were expressed for the lecture delivered by the Rev. Gordon Salmon on "Hardy Fruit Culture," and to the Dean of York for presiding. The report was duly adopted.

Sir Joseph Terry was unanimously re-elected president, but, owing to his sudden decease on the following day, a new president will have to be elected. Mr. Lazenby was again elected secretary. For the minor shows of 1898 £70 was voted, and £170 to the chrysanthemum show. Votes of thanks to the officers of 1897 and to the chairman concluded the proceedings

A Useful Gardeners' Almanack has been published by the Isle of Wight Gardeners' Association. It gives the dates of the various Island shows, and of R.H.S. and N.C.S. meetings, and includes a calendar of garden operations, planters' tables, and list of books relating to horticulture. It is a very handy production.

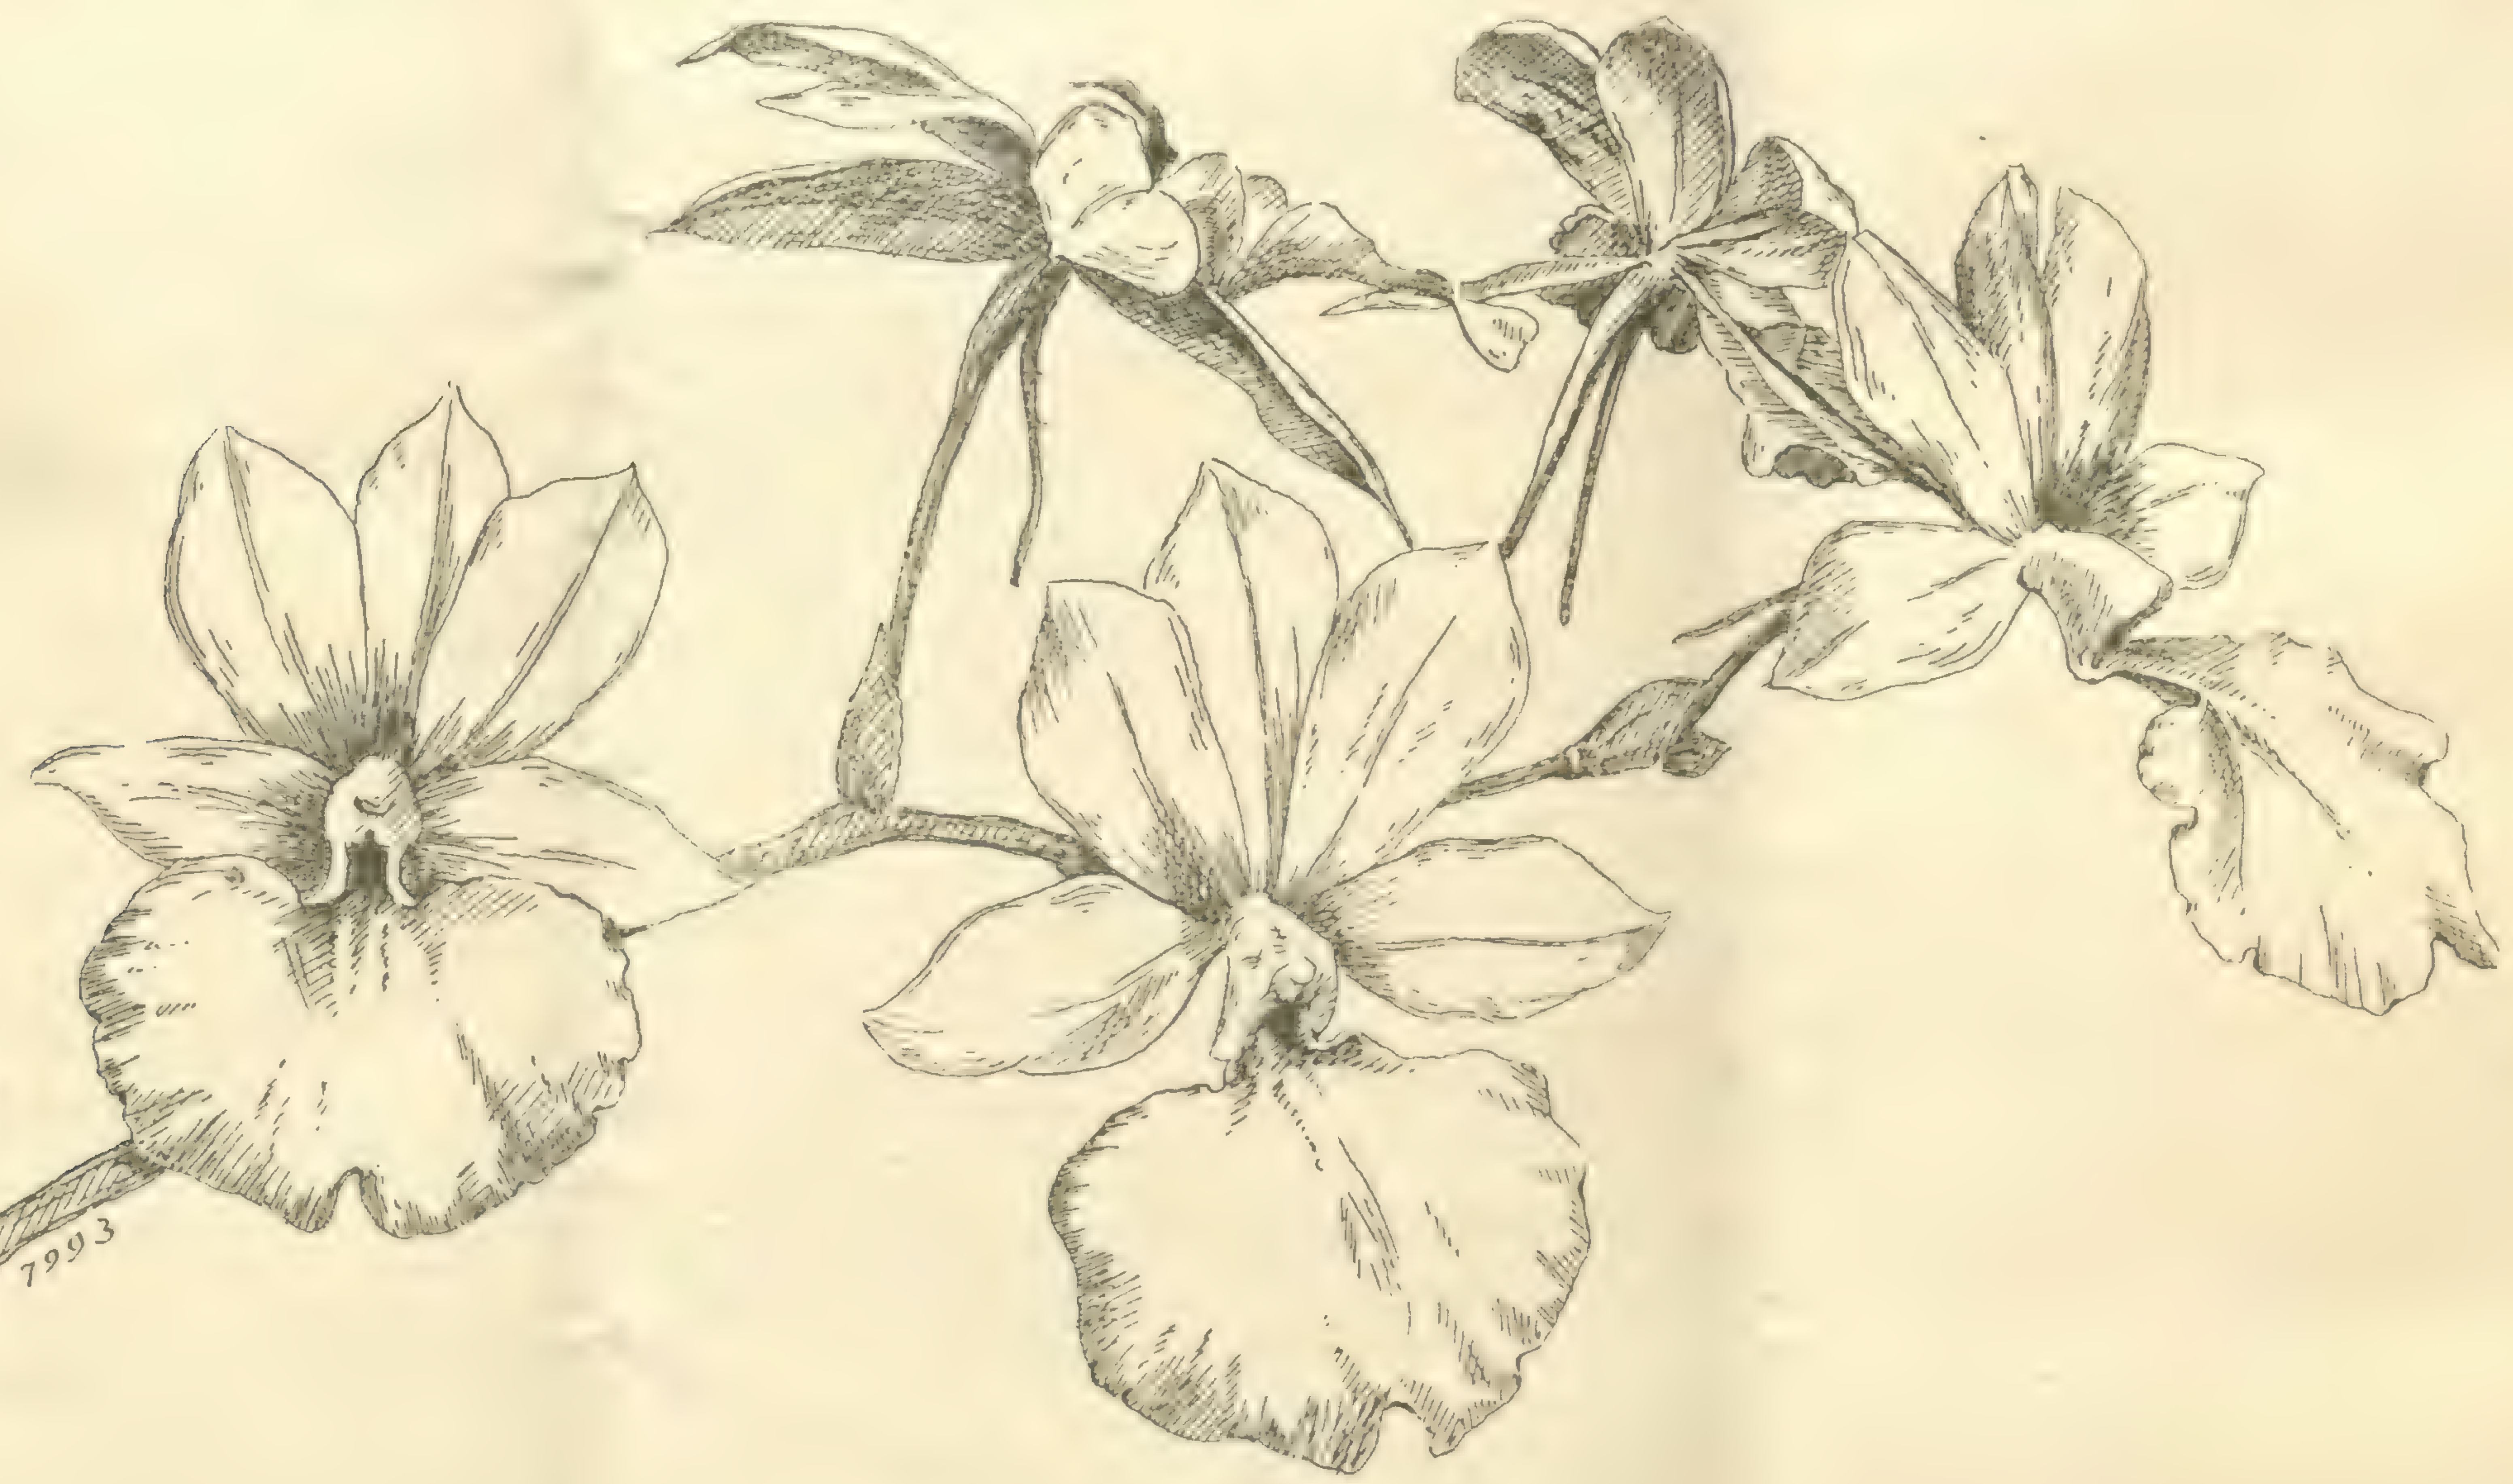
NOTES ON ORCHIDS.

Odontoglossum asperSum.

This orchid is considered by some to be a natural hybrid between O. maculatum and O. Rossi. It will now be in flower in most collections, taking a high position among the smaller growing odontoglossums. The flowers are decidedly attractive and distinct. The pseudo-bulbs are as a rule flatter than those of O. Rossi, but about the same size. It may be grown in pans suspended from the roof in a cool and moist temperature, and an ordinary description of compost suffices if placed over good drainage. This odontoglot is apt to be badly attacked with a soft whitish scale which increases very rapidly and soon disfigures the foliage, but if the plants are washed or sprayed with XL All liquid insecticide whenever any traces of the insects are seen, it will be found to destroy them without injury to the plants.—G. Shill, *New Hall Hey.*

Calanthe Harrisi.

One of the most beautiful and at the same time most rare of calanthes is C. Harrisi. It has pure white sepals and petals, and a rounded labellum that has a shortened base, thus rendering the flower more compact than in most species and hybrids. The lip is pure white, save for the very faintest touch of yellow along the disk; it is also very large, measuring an inch and a half or an inch and three-quarters in width. The history of this fine calanthe is somewhat obscured, though it appears to have been raised by crossing C. vestita Turneri with C. Veitchi. The late Dr. Harris was the raiser, and the specimens were, we believe, bought up, with other orchids, and in an accidental manner, by Messrs. J. Veitch and Sons, Chelsea. It flowered at Chelsea a few years ago, and subsequently a specimen passed into the hands of J. T. Bennett-Poë, Esq., Holmwood, Cheshunt, who is a remarkably successful cultivator, and soon persuaded Calanthe Harrisi to show its capabilities. This plant was exhibited on December 14 last, when it bore a spike of five flowers, as shown in the accompanying illustration. Calanthe Harrisi is the finest white calanthe yet raised, but it will not very soon be generally grown, as there are probably not more than three or four plants in cultivation.



Calanthe Harrisi. (Flowers pure white.)

Oncidium Batemannianum.

This is a species not frequently seen in gardens, but it is nevertheless very bright and attractive when in flower. It frequently blooms during the winter, and is then especially welcome. It has a very tall and stiff inflorescence, bearing a sparsely branched panicle of medium-sized flowers. The latter have yellow sepals and petals, but these are heavily blotched and barred with dull reddish brown. The lip is of a pleasing shade of bright yellow, and has a very complicated toothed crest. This oncidium is also known as O. ramosum and O. spilopterum; it is a Brazilian orchid, and its flowers show some amount of variability. In the case of this species, priority of name has not been considered, for O. ramosum was the title given by Lindley in 1837; but later, when revising the genus, he gave the species as O. Batemannianum, the name given by Knowles and Westcott in 1840. It is much to be desired that this oncidium should become more plentiful.—K. P.

Spiranthes colorans.

Under the names of Stenorhyncus speciosus and Neottia speciosa this curious West Indian orchid has long been known to cultivation. Unfortunately it went largely out of cultivation some years ago, but has recently been again brought under notice, especially by Messrs. F. Sander and Co., St. Albans. It is a terrestrial orchid, often with tuberous roots, from which it can be easily propagated. An intermediate or stove temperature will suit it, and for compost it does well in a mixture of fibrous loam, peat, sand, and a little chopped sphagnum. Good drainage is essential, as moisture has to be plentifully supplied during the period of free growth and of flowering. During the period of rest very little water is necessary, and a good plan is to plunge the pot in a larger one, filling up the space between with soil; water can then be given to the plunging material occasionally, and it will then be conveyed to the spiranthes in such a way as to prevent damping or excessive drought and shrivelling. The foliage of this species is deep green, broadly lanceolate, and fleshy; the spikes are several inches long, and borne on a stout peduncle from four to six inches in height. The flowers are small in breadth, but about three-quarters of an inch long, and scarlet in colour; the bracts are long and very showy, scarlet tipped, shading to pink. Though not so showy as some orchids, Spiranthes colorans never fails to attract attention when flowering, and as spikes may be produced during the early months of the year, it is an orchid worthy of cultivation. The species was introduced about 1790.—C.

ROOT-GRAFTING THE APPLE.

Mr. C. H. Andrews, of the Minnesota School of Agriculture, U.S.A., gives the following directions for root-grafting the apple:—

The object of root-grafting the apple is to propagate varieties true to name, and to get the union of the scion and the stock under the ground, where it will be somewhat protected. The stocks used for root-grafting are seedlings, either one or two years old, the age depending on the size required for the scions. The seedlings for this purpose are best grown on a rich, moist, sandy soil, so as to ensure a straight, vigorous growth. In autumn the seedlings are dug and packed in sawdust in a cold cellar, where they remain until wanted for grafting. The scions must be wood of the previous season's growth, and should be cut late in autumn when the temperature is above freezing, and, after being labelled, packed in sawdust in a cool place.

Grafting may be done any time during the winter. A scion five or six inches long is cut off at one end in an oblique direction, making the cut surface about an inch or so long, then a tongue is made by splitting down across the face of the cut about one-third of its length, beginning at a point about that far from the end of the scion. A piece of root four or five inches long is treated the same way as the scion was, and the two are then united, care being taken that the inner or cambium layer of the bark of the scion and the root coincides on at least one side of the union. The graft is now wrapped with waxed twine, or wax may be spread upon cloth or paper, which is then cut into strips and firmly wrapped around the union, also above and below it, so as to exclude all air. The latter method keeps the graft from drying out and does not cut into the bark after the plant grows. The grafts are packed in boxes in a mixture of sand and sawdust, and are kept until planting time in a cold cellar to callous over and grow together.

The land where they are to be set should be finely pulverised and rolled or planked to level the surface. As soon as there is no danger of a severe frost, the grafts may be planted. They are usually put six or eight inches apart in rows three or three and one-half feet apart, running the rows north and south. All shoots that may have started from the root should be rubbed off. In planting, the earth must be packed very firmly around the graft, which ought to be set deep enough so that only one or two buds will show after the ground has settled.

Cultivation should be frequent in order to kill the weeds and to keep a dust blanket on the soil, but it should not be continued later than the tenth or the middle of July, as it is likely to induce a late autumn growth that cannot be ripened up. The grafts require no pruning the first year. Early in the spring of the second season they are cut back to one or two buds, and a straight shoot is sent up, which is pruned later to make it head properly. The third season the pruning done is merely enough to keep the tree in proper shape. The growth the trees make depends a good deal on the soil, the season and the variety. Yearlings run from one foot or less to two feet in height; two-year-olds, from three to five feet; and three-year-old trees, from five to six feet. These trees after the first year develop some roots of their own, and they are thus better able than they otherwise would be to withstand a rigorous climate.

LEAVES FROM A RAMBLER'S NOTE-BOOK.

THROUGH ORCHARDS AND BRICKFIELDS.

RATHER a strange combination perhaps you'll say, and so it may be, though interesting by contrast. Fruit growing and brick making are not occupations that one would naturally class together, but anyone travelling in that part of Kent extending from Chatham to Faversham could hardly take notice of one without being struck by the extent of the other, no matter whether seen out of the eyes of a gardener or a builder. Those whose occupation is connected with bricks and mortar know the district well, and are acquainted with the excellence of the clay for the manufacture of building material ; therefore it is the great kilns, the somewhat choking atmosphere that arises from them, the huge mountains of bricks of varying quality, and the all-important question of prices that claim the attention of the builder. The gardener and he who is interested in fruit culture sees matters from his own point of view. Bricks are nothing to him, and his interest lies in the orchards. To some extent they are inseparable, however, and one follows the other in quick rotation. First comes the brick-maker with his smoky kilns, his plant for clay grinding, and all the rest of it. He takes sole possession of a tract of land, and in course of time the top crust, of a thickness varying from six feet, disappears, goes through the process of grinding, moulding, and baking, and then plays its part in extending the arms of the great metropolis further and further into the country. Under ordinary circumstances a disused brickfield becomes a desolate region where rank grass only grows and pit-holes stand full of putrid water. The old kiln falls down a little at a time, and decay is plainly written on the whole surroundings. It is not so in East Kent, for no sooner has the brick-maker taken all that is of any good to him, when along comes the fruit farmer to reap his share—and often a golden one, for some of the most valuable orchards and plantations in the country occupy sites that once were brickfields.

This speaks volumes for the fertility of the soil in this part of Kent, and its adaptability for fruit growing. Go anywhere else you like, north, east, south, or west, and find land that will first make bricks and then grow fruit. I don't think you'll succeed ; and mind you, I don't mean fruit of the common order, small in size and of inferior quality, but first-class specimens—Pitmaston Duchess pears, averaging over a pound each ; Cox's Orange Pippin apples, that fetch the highest price in the market ; cherries that are the cream of British production, and find their way into every town of any size in the land ; not to say anything of the plums and small berried fruits, such as gooseberries, currants, and raspberries. Not all grown on disused brickfields, of course, as the land everywhere grows fruit, and grows it well ; but so close does the planter follow in the wake of the brickmaker, that almost before the latter has removed his stock-in-trade, the plough or steam cultivator is at work. And is this in our poor old worn-out England, you ask, when at the end of the nineteenth century, and the cry that land cultivation is played out is for ever booming in our ears, we still have land that will make bricks and then grow fruit? The answer is in the affirmative, but not without an effort on the part of the cultivator in preparing the land, growing the trees on the most approved principles, and above all, feeding them. "Manure! that's the secret," said a successful grower, "and plenty of it ; not always stable manure, though you need not be afraid of using that, but now and then a change in the way of a good stimulant of chemical manure." One is apt to get depressed in these days, and the story of "Wasted Orchards," so graphically depicted in these columns, told us of the ground we are losing, and the improvements that must be made to regain it. Fortunately there is a rosy as well as a seamy side ; and one begins to think that "things are not altogether what they seem," when a farmer who grows some two hundred acres of fruit comes forth and says the last was the best season he has ever had.

Such was the statement voluntarily made ; and I confess to looking in astonishment at a man—a farmer and cultivator of land for many years, in the midst of this never-ceasing cry of agricultural depression—sitting by my side, and calmly asserting that the season of 1897 was the best he had ever had.

"I've got some poor land, of course," he said, "that pays but very little ; but the other makes up for it, and some of my best plantations have been brick fields. Pears, apples, cherries, currants, gooseberries, and strawberries have all done well," he added ; "and as to prices, well, the worst apples I've got, which in former seasons I've been content to sell in the neighbourhood for what they would fetch, have all gone to London, and the prices I obtained paid well for sending them."

I know something of the grower and something of the farmer, as well as something of the business methods adopted to carry on the whole concern, and conclude that this must have a great deal to do with the success.

"I think farming is looking up," was his opinion, "and we are getting back to something like the old prices. Corn has gone up, potatos are selling well ; and as for fruit, well, I'm getting seventeen shillings a bushel for Cox's (Orange Pippin apple was meant), and I wish I'd got tons of 'em."

Seventeen shillings a bushel for apples is by no means a price to be despised, and even at a much lower rate, with an average crop, there is something to pay the rent. It is the best that commands the highest price, and whereas the king of dessert apples will always find a ready market at a remunerative price, there are numerous other sorts still grown and will hardly pay expenses. Still, some growers stick tenaciously to them, but why it is difficult to imagine. The fruit mentioned was sold in the open market, and that was the price handed to the producer. I almost dread to ask what the price would be when they reached the consumer, after the middlemen had taken their share.

"Did cherries do well last year?" I asked. "If you had any, yes," was the reply. "I was fortunate, and I daresay you won't think that a hundred pounds an acre is a bad return. But everybody wasn't so well off, as the hailstorms in the early part of the season played such havoc and ruined a good many of the crops. Prices for standing orchards ran very high, and just to give an idea of the value of the fruit an orchard of cherries—old trees some of them, really past their best—was sold freehold. It was five acres in extent, and fetched twelve hundred and fifty pounds. It will have to return something to pay an interest on that. Eh?"

Two hundred and fifty pounds an acre for land planted with cherries! And this, mind you, occurs when everybody is talking of bad times and when some go so far as to say that fruit growing is overdone. At this rate there still appears to be something in the shape of a Klondyke even in the old country. My informant went on to say that if the land in question was worth two hundred and fifty pounds an acre, he knew of other orchards worth double that amount, where the trees are younger and just at their best.

"And how does corn-growing compare with that?" I inquired.

"Not in it with good fruit. At any rate, that's my experience, and I've just planted another ten acres of cherries and the same with apples and small fruits. Black currants did splendidly last year, though in some places they were scarce. Fourteen shilling a half isn't bad ; at any rate, I'm satisfied. And as for gooseberries, I found Lads (Lancashire Lads) did the best with me. I'm planting a lot more of 'em." Here it was suggested that perhaps, if planting continued so rapidly, the thing might be overdone.

"Never," was the emphatic answer ; "there's always a demand for good fruit, because every year there is more consumed." In the remark there was a ring of confidence that told the man knew what he was talking about.

That the industry is developing is evident when one realizes that in this land of bricks and fruit, private growers have amalgamated and formed limited liability companies, with capital running into the thousands. Special trains carry their burdens of fruit in season, not only to the near metropolis, but right through its limits and on into the smoky manufacturing districts of Lancashire and Yorkshire ; and not even content with that, fruit that yesterday was ripening in Kentish fields and orchards, is to-day across the border and being dealt out to the dwellers of Glasgow and other Scottish towns. The growers speak of their gooseberries as "Lads" and "Bobs," their cherries also bearing familiar abbreviated names, and their apples are known as "Suffields," "Warners," "Kings," and "Cox's." The orchards and plantations are pretty sights, either in fruit or blossom ; but to the ordinary observer, the sulphury smell, or the dusty smoke from the brick-kilns detract largely from the beautiful, and it is hardly the place one would recommend for scenery. Close to the water, the tides in the creeks rise high and fall low, leaving murky-looking pools and ugly mud-banks, and up these channels comes the returns from the metropolis, in the shape of manure laden in barges. London manure has nothing of the wholesome stability about it that characterises that fresh from the farmyard ; but the soil is naturally good, and it does its work, especially when assisted by other stimulants, among the hops, the fruit, and potatos.

"Sold my potatos to-day," said one grower, in the midst of conversation ; "Up-to-Dates ; thirty-four pounds an acre. Not bad, that?"

No, not at all bad ; and what say those pessimists who assert that there is not a ray of hope left for English cultivators? It also speaks volumes for the heavy cropping propensities and general excellence of the variety which, as it becomes more widely known, is increasing in popularity. Up-to-Date it surely is, in more ways than one, as thirty-four pounds an acre is something new, and to the grower sounds something like old times in the golden days of farming ; and moreover, it seems to suggest that after all there are hopes that the time-honoured occupation is looking-up.

It is urged that farmers generally are slow to grasp new ideas and abandon old methods, but the same cannot be urged against the East Kent fruit grower. You find him a shrewd, clear-headed man of business, ever ready to pick up a wrinkle if it can be turned to profit. He has to be very much alive, too, in order to arrange his labour at fruiting time, and keep disposing of his supplies. Any delay when perishable fruit is about is disastrous ; and one man informed me that at Jubilee time, when everybody was holiday-making, his strawberries were spoiling for the want of gathering, and in order to get pickers he had to pay them as much as ten shillings per day. Another grower thought he saw something in large early culinary apples, and so planted Lord Suffield, Warner's King, and several others, on a large scale. Some people thought hops would be better, and others were in favour of the time-honoured corn ; but our friend said little, and in the meantime his sturdy bushes on the Paradise stock grew quickly into bearing, and, to use his own words, they are now doing him good. He also goes in for pears, and on the old brickfields grows fruit worth going a long way to see. The ordinary tourist who loves romantic scenery or historic associations can better satisfy his desires in other directions ; but anyone who is interested in fruit would find much that would engross as well as instruct just out of the sound of the hammering at Chatham dockyards, and within hearing of the gunnery at Sheerness, even though in the midst of the fruit he is being constantly reminded of the presence of bricks.

H.

KEIR GARDENS, PERTHSHIRE.

One of the most interesting and enjoyable days I have ever spent in a garden was during last autumn, and the place was Keir. Mr. Lunt, is well known in Scotland as one of the best of gardeners, and also as one of the most successful exhibitors of garden produce at Edinburgh, Glasgow, and Stirling shows. He is a most enthusiastic and broad-minded horticulturist, and is happy in serving a gentleman who is devoted to his garden.

The Keir mansion and surroundings command some of the most lovely scenery of Perthshire. From the terrace fine views are obtained of Stirling Castle, and the scene of the battle of Bannockburn; in the distance one has a glimpse of the Firth of Forth and the Wallace Monument. Beautiful moorland slopes clothed with heather, and varied in outline, lead down to the immediate foreground of the valley through which runs the river Teith, winding in a charming manner and joining the Forth near Stirling. These views all combine to form some of the most picturesque Scotch scenery. From another point, views of the mountains around Callander, the Trossachs, and Ben Lomond, are very fine; in fact, fresh peeps and charming landscapes are continually being presented in a walk round the extensive and well-kept grounds. Fine specimens of various coniferæ abound, and one of the finest to be found in the country is a European larch. The tree is supposed to be one of the first planted in Britain, early in the seventeenth century. Some fine Douglas firs were conspicuous, and very noticeable were many trees of Pinus Laricio, evidently one of the most profitable pines to plant for timber, as these were almost double the size of Scotch firs planted at the same time, and had clean upright boles. Abies grandis has been largely planted, and many fine specimens occur. Two extra large trees were Pinus insignis and Abies Smithiana.

In the grounds the only objectionable feature is the survival of a very large number of clipped trees and hedges, many of the latter apparently serving no useful purpose, except to show the extreme folly of a phase of garden work which was popular in a bygone age, and which we may hope will never be revived. In every possible nook and suitable place, bulbs of all kinds are planted year by year, in the grass and by the sides of a pretty streamlet which wanders through a portion of the grounds to join the river Teith. Hardy, strong-growing herbaceous plants, in association with flowering shrubs, are naturalised in bold groups on banks and in rough grassy places. These constitute in their seasons most interesting features, and the idea is being gradually developed and the planting extended. Herbaceous flowers are being cultivated with much zest, and a fine collection of species and varieties are grouped in a large border near the mansion. Early border chrysanthemums are much appreciated, and so are the numerous kinds of Michaelmas daisies.

The kitchen garden and glass department occupy a southern slope, and are of considerable extent. The past season had not been very favourable, owing to the cold and wet months of June and August. It may be interesting to show the comparison of the rainfall at Keir and New Barnet for the first nine months of 1897: At Keir—January, 1.68; February, 2.87; March, 4.92; April, 2.08; May, 2.60; June, 5.99; July, 1.75; August, 6.25; and September, 2.83 inches. New Barnet—January, 2.68; February, 2.61; March, 3.95; April, 1.74; May, 1.64; June, 3.19; July, 1.25; August, 3.11; and September, 3.15 inches. This will show how much better our season round London was for many things than that of the east of Scotland. Mr. Lunt is full of enthusiasm for chrysanthemums, and grows a large number. Though these are always a fine lot of plants the blooms are not so satisfactory as is desirable for the keen competition encountered in Edinburgh cup classes. This, however, will certainly be remedied in future seasons if skill and attention can avail against a somewhat ungenerous climate. The records of the past two years' exhibiting show good results, but Mr. Lunt is ambitious, and threatens to win still more and higher honours.

In the fruit houses, where in their season the chrysanthemums are arranged, first-rate examples of vine culture were to be seen. Young rods of Muscat of Alexandria, bearing splendid bunches of highly-finished fruit, and Black Alicante, Alnwick Seedling, Lady Downes, and Mrs. Pince were also in fine condition. The pride of the Scottish gardener is his grapes, and in this case there was ample justification for the pride. The temporary vines grown in boxes were really marvels of high cultivation, and were carrying about ten or twelve pounds of first-rate fruit. The boxes were only about two feet by one and a half by one foot, and had stood on open staging, so that no rooting outside was possible. It would be extremely interesting if Mr. Lunt would give us the details of his treatment of these vines in an early issue of the Gardeners' Magazine. In another house containing old vines some most interesting examples of the influence of the stock over the scion were pointed out. For instance, the flavour of Madresfield Court had been spoiled through its being inarched on Foster's Seedling. Lady Downes grafted on Black Alicante produced berries quite oval in shape, and of a distinctly Alicante flavour. Lady Downes on White Chasselas was much improved in flavour, and had a thinner skin than when grown on its own roots. On an old rod of Mrs. Pince there was hanging a bunch with very much larger berries than in the type, and which appeared to be a sport. Should such prove the case and the variety be propagated, it will be sure to take high rank amongst the late-keeping black grapes. The peaches were perfect examples of good training, and as evidence of the excellent crops they have borne, I may state that many fruits of Royal George have exceeded nine ounces in weight, and of Sea Eagle thirteen-ounce fruits were gathered.

In the plant houses numerous large specimens of various palms and fine foliage plants are grown. One house devoted to crotons contained grand plants, highly coloured and well furnished with foliage. Large examples of anthuriums, alocasias, marantas, and many good things were strong testimony of the care bestowed in their cultivation. Hard-wooded plants are much prized, and young specimens of all the best species occupy a cool house with large azaleas and Himalayan rhododendrons. Cyclamen are a feature, too, and grown to perfection at Keir.

The foregoing remarks are but a suggestion of the many instructive and well-managed departments of a good garden, the inspection of which will afford the utmost gratification to those who may have the opportunity of visiting it.

Trent Park Gardens. W. H. Lees.

BLUE IN FLOWERS.

When Mr. H. Knight, in his interesting paper, "The Blue Chrysanthemum," published on page 19, refers to the changeable colours of the Cheiranthus chæmælus, does he mean the species better known in gardens as C. mutabilis? He also refers to the changeableness of hue found in a forget-me-not (*Myosotis versicolor*), but similar changes, only in the reverse order, are often seen in M. dissitiflora, as I have found scores of times floral branches that had red flowers, so varied from blue. I have tried saving seed from such and perpetuating this rich colour; alas! in vain. Usually such changes, I think, have come from some slight bruising or injury to the stems. One of the most interesting changes produced solely by root drought is that seen in the pretty mossy Sedum lydium, which is normally bright green, but which in hot dry weather turns to a rich red. What an effectual hardy carpet plant would this be could it be so normally coloured. All variations in colour without doubt are due to changes in the body of colour, or reflective granules, found in the flower petals. We see this change produced in a remarkable way in the garden hydrangea, when plants normally carrying pink flowers get transferred to soil that contains iron or other minerals in considerable quantity, when the flowers come of a rich blue colour.

It is rather surprising that with a knowledge of this fact no one has, so far as I am aware, attempted to chemically convert pink chrysanthemums to blue ones. I do not say that such change is practicable, but has anyone experimented? That is an assertion open to much question, which Mr. Knight makes on the authority of eminent botanists and scientists, that blue flowers represent the most highly developed lines of descent which have, or whose ancestors have, passed successfully through all the intermediate stages, which are yellow, red, and purple to blue. If that be so it would seem as if we ought to find blue a colour development in a very marked degree in cultivated flowers, and especially in those much intercrossed and of long descent. Putting aside the chrysanthemum—which is in Europe a comparatively youthful plant, although very old in China and Japan—we find the blue rose, or blue dahlia, carnation, hollyhock, and some other popular flowers of long existence to be as far off as ever. All those have got into purple pretty well, but the dense blue tint seems to be as far off as ever. On the other hand, how very few cultivated plants are there that have, even over a long series of years, developed blue, except those which do so seem to inherit that colour from their original species.

The intense blue of the gentian, or Salvia patens, or of Scilla siberica, or of Vanda cærulea, or of the forget-me-not, are all derived from progenitive species, or are pure species remaining unchanged. The well-known Centaurea cyanus, one of the most marked of the wild flowers, is less robust and more imperfectly developed than are garden members of the centaurea family. How beautiful is the blue of Veronica chamædrys of our fields, or the much richer blue of Phacelia campanularia of another clime; indeed they are blues which no evolved plant seems to have produced. The question after all in relation to these popular florists' flowers, roses, dahlias, carnations, chrysanthemums, and others is, Can we ever hope to evolve blue colour from them by any intercrossings? Even the Japanese blue chrysanthemum, with that nation doubtless the effort of centuries, seems to have existed only in the imagination of an artist. Unless change to blue can be effected by the application to the soil of certain chemical compounds, then does other effort seem useless. A. D.

[The wallflower Mr. Knight referred to is, correctly speaking, Cheiranthus scoparius var. chamælo, a native of Teneriffe. C. mutabilis also is changeable, as its name implies.—Ed.]

Hardy Peach Culture.—On page seven of the Gardeners' Magazine for January 1 there is an excellent article upon peach growing, but being very much interested in this work, I should like to make a few remarks upon it. "Kentish Gardener" says: "for outside walls a coping is necessary to bring about good results." So far, so good. But I believe in no coping beyond the ordinary four-inch stone coping, which is just enough to keep the wall dry and the trees from drip. A glass coping is sometimes a little advantage in helping to ripen any late varieties during October, because at that period the nights are damp, and the trees do not require much assistance beyond that of gathering the fruit. I have seen most wretched specimens of peach trees that have been coddled up under glass copings, and when the latter are fixtures, they are worse than ever, for they help aphis, thrip, and red spider to multiply at an alarming rate. This may have been largely the fault of the grower in not attending to the syringing, watering, &c., required daily by such trees. Being fixed close to the wall, drip was kept away, and the foliage at the top on a hot summer's day is nearly baked. Many people think that a coping is necessary for outdoor peach growing, but I strongly advise anyone to try for themselves, and not let the expense of providing a glass coping stop them from peach growing on an open wall. We manage to obtain a good supply from July till October from outdoor trees *without* the aid of a glass coping, and our trees are always admired for their vigorous and healthy growths. "Kentish Gardener" lost sight of two of the most important varieties that we grow outside; Waterloo, the earliest of all; and that good all-round peach, Dymond, which I consider second to none, being handsome, prolific, and fine flavoured.—W. A. Cook, *Compton Basset.*

NEW WINTER-FLOWERING BEGONIAS.

THE production of the tuberous begonia as we now know it is certainly one of the greatest horticultural feats of the present century, but with all the vigour of growth and variety of colour and form the race possesses, none of the varieties are amenable to winter cultivation. They are essentially summer and autumn flowering plants, splendid for their season, but not assisting to dispel the gloom of our winters. Many a horticulturist, watching his tuberous begonias in the conservatory in June or July, has thought what a grand thing it would be could such a display be produced during either of the four months of October, November, December, and January. One, at least, did something more than think; he set to work, and his efforts have resulted in the production of an entirely new race that bids fair to become as essential at the end of the year as cyclamen and primulas are at the beginning.

The raiser of this new race is Mr. J. Heal, the capable and genial hybridiser at Messrs. J. Veitch and Sons, Chelsea, whose efforts in connection with Javanese rhododendrons, hippeastrums, streptocarpus, and phyllocacti are well known. How to make a decided start toward the end in view was a difficult matter to decide, for though by selection and retarding tuberous begonias could be made to flower fairly late in the year, yet they were not produced late enough; the declining light paled the bright hues so resplendent in summer, while autumn fogs spoiled the whole crop of flowers in an hour or two. The difficulty was practically solved by the discovery of Begonia socotrana by Professor Bailey Balfour in 1880. Some plants were sent to Chelsea from Edinburgh in 1881, and its winter-flowering propensities having been tested it was put into commerce by the Messrs. Veitch the following year. This species, then, offered a basis whereon to build a race of winter-flowering begonias that would stand a large amount of fog uninjured. But to find tuberous begonias with which to cross B. socotrana was no easy matter, and having found them, other difficulties arose, for the begonias are widely different in habit, this species having clusters of bulbils forming at the base of the annual stem, and the others having a tuberous stock. However, as in many other instances, Mr. Heal's perseverance overcame the difficulties, and his first new begonia having the above for parents was the now celebrated B. John Heal. Other varieties followed, and quite a new lead was made in 1895 when B. Mrs. J. Heal came before the public; subsequent varieties have been more robust and showy than the earlier ones, and they show the wisdom of reverse crossing.

The method of cultivating these winter-flowering begonias is practically the same throughout, though there are slight differences to be considered in propagating the several varieties. Thus B. John Heal and B. Winter Gem partake largely of the character of B. socotrana, especially in having bulbils; B. Adonis has no bulbils, but it can scarcely be called a tuberous variety, though the dormant root stock thickens somewhat. B. Mrs. Heal, B. Myra, B. Ensign, B. Julius, B. Success, and B. Winter Cheer, are all tuberous rooted, and can be propagated by cuttings of the young growth. An intermediate temperature suits this family all through the year, and they need abundance of light and a position as near the glass as possible. In the matter of soil they all succeed in a compost consisting of two-thirds fibrous loam and one-third peat or leaf-mould; to this should be added a liberal allowance of sand. Large pots are a mistake, and even for such a strong grower as B. Adonis a thirty-two size is ample for the final potting; for most sorts a large forty-eight is sufficient, and it is surprising what growth and profusion of bloom can be then sustained. As regards temperature, the thermometer may register 60 to 65 degrees in summer and 50 to 55 degrees in winter. The tubers remain dormant during spring and summer, starting into growth about the end of July and during August. Cuttings may be rooted in a close case in a warm house any time during the autumn, but for the purposes of increase it is a good plan to start a plant or two in June, as the early growth thus produced will give cuttings that root in July, and flower, if kept in small pots, during winter. Very little water is necessary during the dormant stage, but the tubers should not be allowed to dry as in the summer-flowering tuberous forms. A good plan is to plunge the pots into others a size or two larger, filling the space with soil; an occasional damping of the stage will then be sufficient, provided the atmosphere of the house is not excessively dry. Plenty of moisture is needed when growth is free, and to assist the development of spikes and flowers weak guano water in occasional doses will be found desirable. Green fly has to be kept down by the usual means, but very strong fumigations are not favourable to the plants. Now as to the varieties.

B. JOHN HEAL, the first of this race, worthily commemorates the raiser. It was awarded a first-class certificate by the R.H.S., on October 13, 1885, and put into commerce in 1888. It was the first successful hybrid between a tuberous begonia—the variety was Viscountess Doneraile—and B. socotrana. It has bulbils very much as in the seed parent. It is a dwarf variety, with medium green foliage, and bears light racemes of bright rosy carmine flowers, each an inch and a half across, and borne six to nine together. A remarkable point in this begonia is that a female flower is extremely rare, and this to some extent accounts for the persistence of the crop, as individual flowers last about three weeks in good condition, and then shrivel on the raceme instead of falling. For table decoration this is a splendid begonia, as beautiful little plants suitable for filling ornamental vases can be grown in large thumb pots.

B. ADONIS made its bow to the public on November 8, 1887, when it was awarded a first-class certificate by the R.H.S. It is a very robust variety, and the result of crossing a summer-flowering tuberous begonia with B. John Heal. The foliage is bold, but still shows signs of the B. socotrana influence, though the root stock is slightly tuberous, and no bulbils are formed. The flowers measure two to two and a half inches in diameter, and are borne in semi-pendulous racemes; in colour they are bright rosy carmine, with a tinge of scarlet; paler centre. B. Adonis was first distributed in 1888.

BEGONIA WINTER GEM, though not put into commerce until 1891, after having been certificated on January 13 of that year, was, I believe, the second of the hybrids produced. It is a beautiful little plant, obtained by crossing B. socotrana with a crimson-scarlet tuberous begonia. It closely resembles B. socotrana in its peltate foliage and bulbils, but it is dwarfer than the species, and has leaves half the size of the latter. Propagation in this case is effected by separating the bulbils, and by means of leaves pegged down and the ribs severed. The flowers of B. Winter Gem are of a rich scarlet-crimson hue, about two inches in diameter, and borne in corymbs on stout erect peduncles. The flowers of this variety are of the most persistent character, lasting in beauty from four to six weeks.

B. MRS. HEAL is a hybrid between a tuberous variety and B. socotrana, the former being the seed parent. This and the following varieties differ from the foregoing in being more robust growers, and producing larger and more showy flowers. It is the finest of the forms yet in commerce, and was quite the centre of attraction when exhibited by Messrs. J. Veitch and Sons, before the R.H.S., on October 15, 1895, when an award of merit was granted. It is distinctly a tuberous variety, but the influence of the pollen parent is seen in the persistence of the carmine-scarlet flowers, reduction of the foliage and lateness of flowering. The blooms are three inches across, substantial, and borne six or seven together on erect peduncles that rise above the light green foliage. The GARDENERS' MAGAZINE of November 23, 1895, contained a figure of this fine begonia. B. Mrs. Heal was put into commerce in 1897.

B. SUCCESS, though gaining an award of merit on October 2 1895, has not yet been distributed. It is, however, a handsome hybrid, having B. socotrana as the pollen parent, and a rose-pink tuberous variety as seed parent. It is a fine addition to the winter-flowering race, its semi-double flowers being of a rich carmine, scarlet-shaded hue, and measuring three inches in diameter.

B. ENSIGN is both beautiful and interesting; the former because its semi-double flowers are finely-shaped and of a bright reddish-pink colour. It is interesting because its mother was B socotrana, and its father a "single" tuberous form. B. Ensign gained an award of merit on November 24, 1896, and was first sent out in 1897. It is extremely compact in habit and already a favourite.

B. MYRA is a bold and free-flowering hybrid, with the same parentage as B. Ensign. It bears large racemes of rosy-carmine flowers, which are chiefly mule; these latter are nearly three inches across, and very persistent. The female flowers are somewhat smaller and scarcely so bright in colour. B. Myra was put into commerce in 1897.

B. JULIUS brings us to quite recent times, for it was exhibited on November 23 last, and on that occasion gained an award of merit from the R.H.S. It is a grand variety, robust in habit, with bold deep green foliage and handsome double flowers of a soft rose-pink shade; the half-opened flowers are extremely pretty. The racemes are freely borne and the flowers numerous, each about two and a half inches across, very persistent, and of wonderful substance. A rose-coloured tuberous variety was the seed parent, and B. socotrana the pollen parent of B. Julius. For this variety horticulturists will have to wait awhile.

B. WINTER CHEER is the latest addition to what may be called the Chelsea begonias. It bears a profusion of carmine flowers tinged with scarlet, and with a salmon centre. It is a semi-double variety, and as the flowers are three inches in diameter, it can well be imagined that it is the most showy of the semi-double forms. It is a tuberous-rooted variety, and, as in the previous form, had B. socotrana as seed parent. Growth is strong and the foliage bold, as in B. Adonis, so that it is probable distribution may commence at an early date. B. Winter Cheer is well named, for it is most effective during winter, and its branching racemes of bright blooms afford a cheerful display. In grace of habit B. Winter Cheer is not excelled by any of its race. A good illustration of its habit and mode of flowering is given in the present issue. C. H. C.

FARMYARD AND STABLE MANURE.

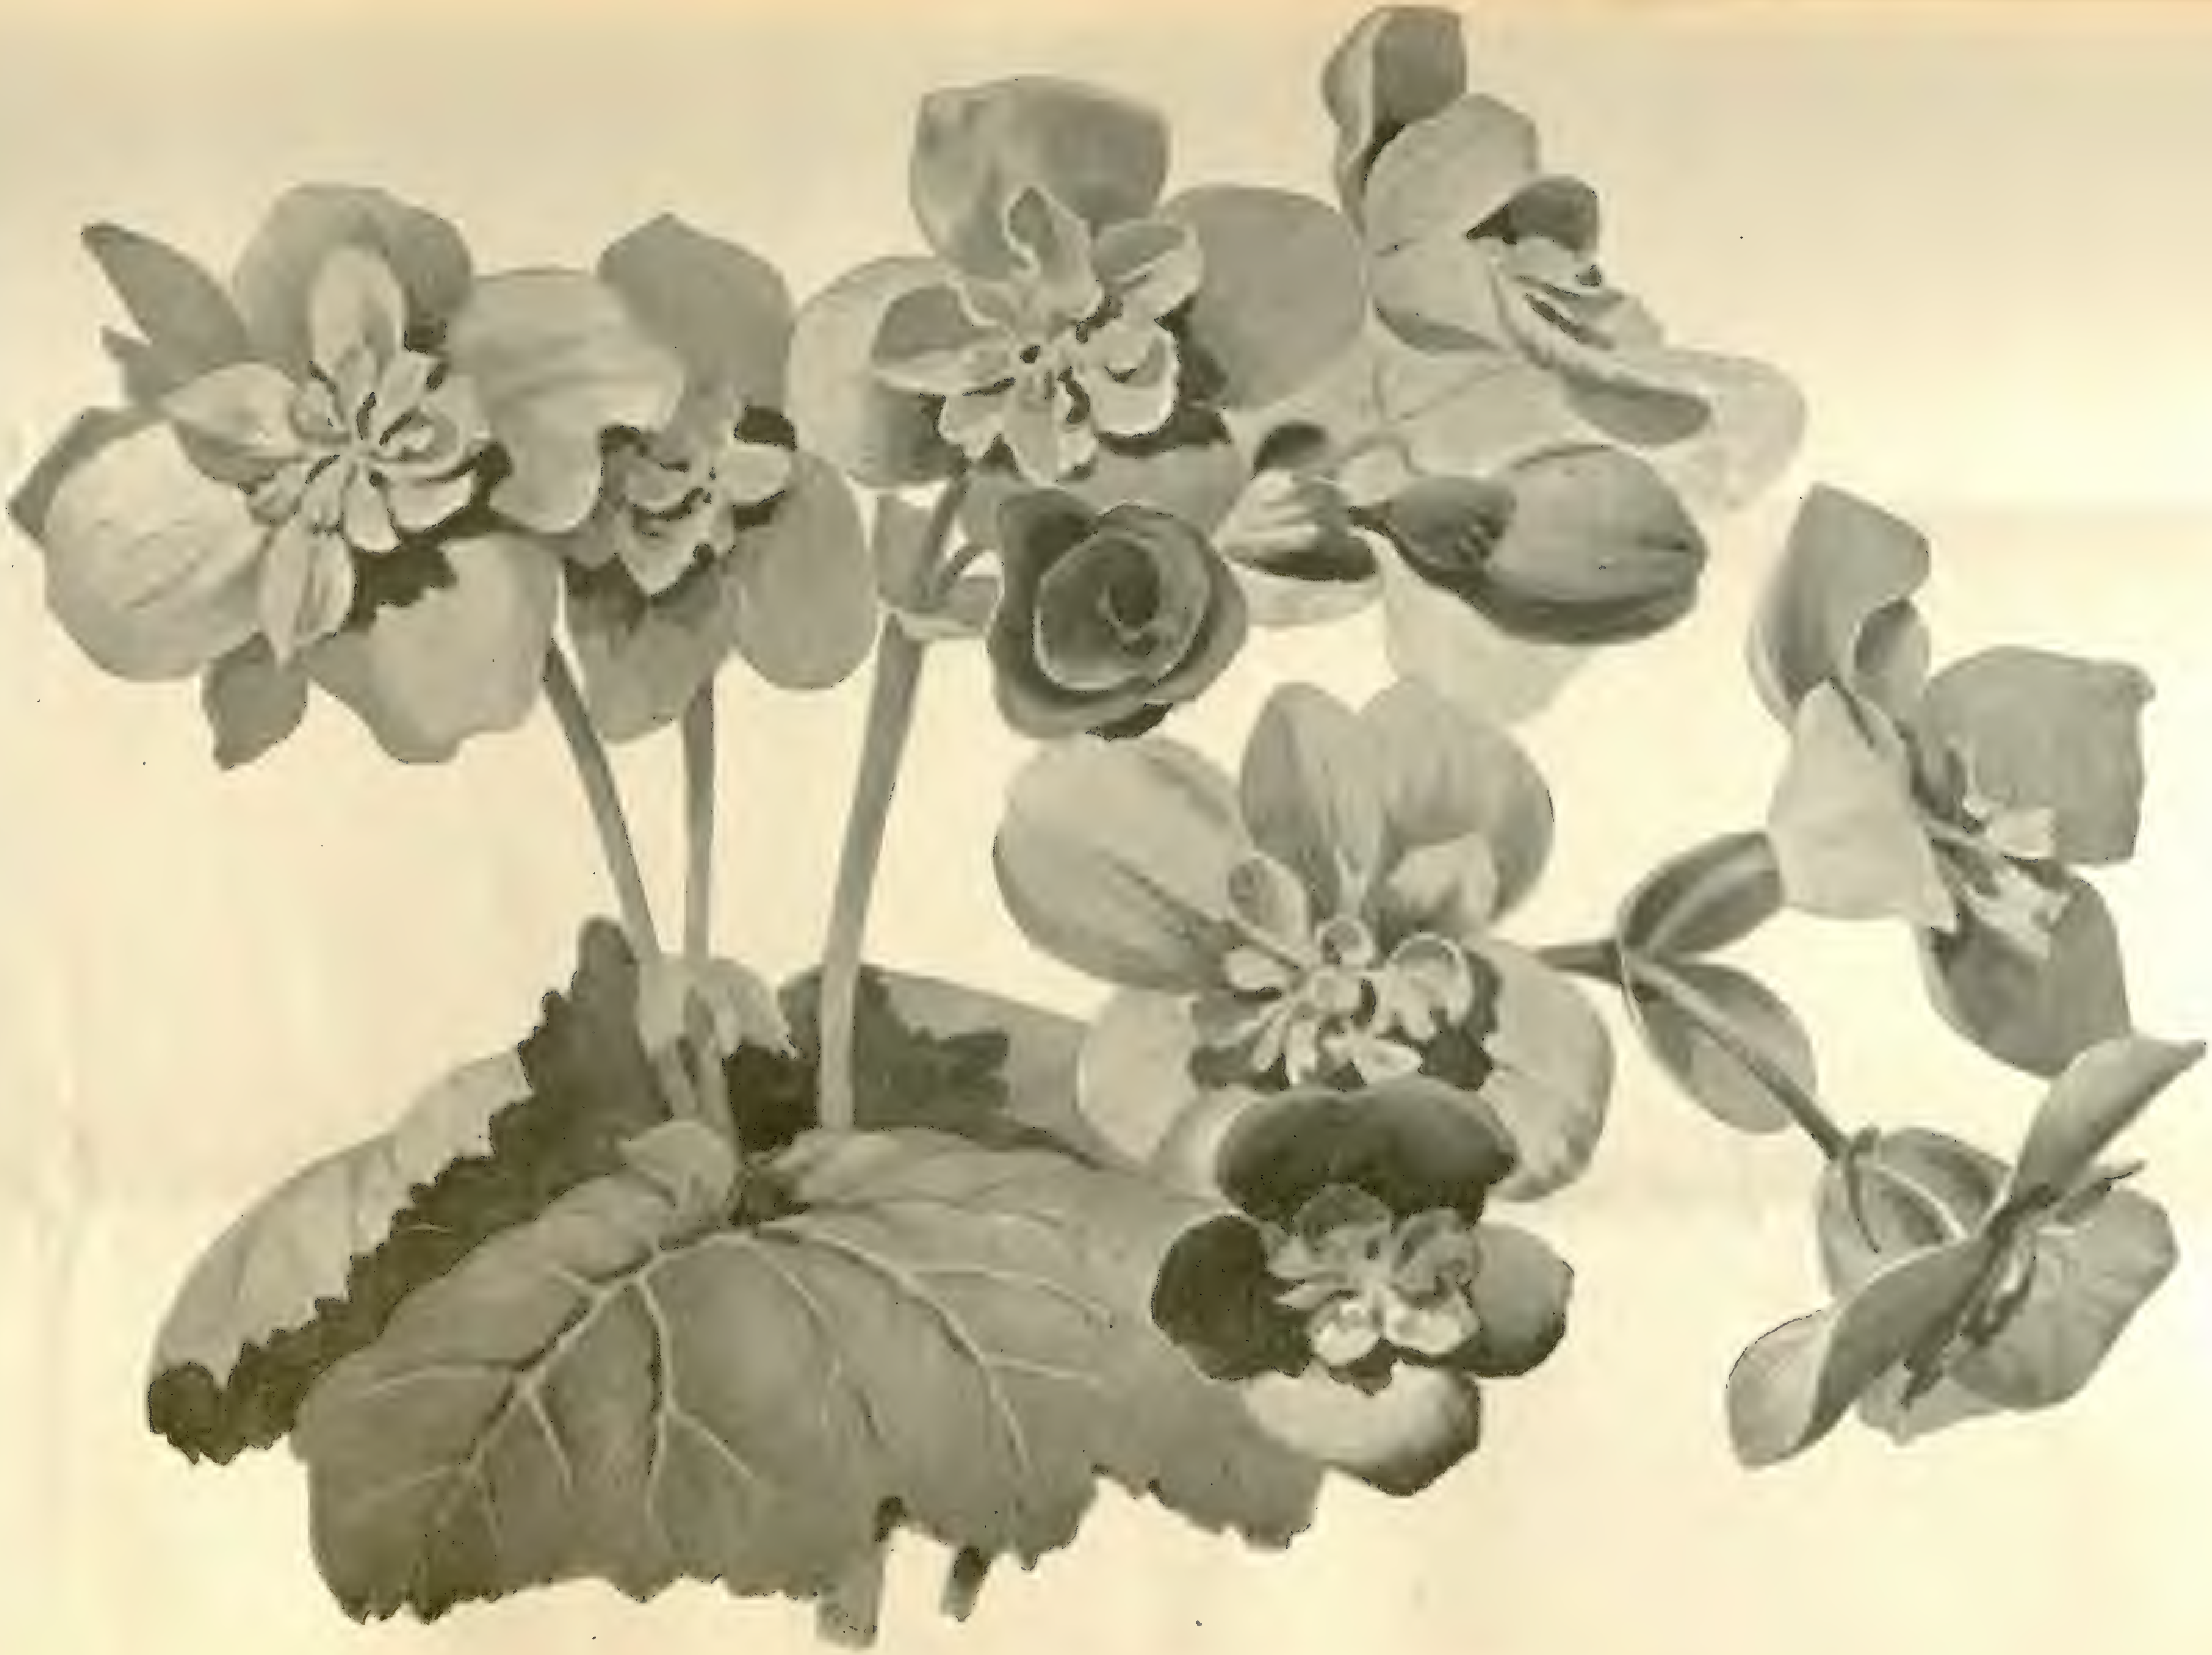
THE whole subject of the economic preparation and preservation of farmyard and stable manure is being actively investigated at the present time in Germany. The fact which has already come into great prominence is, that ordinary farmyard or stable manure are valueless as food for plants until they have been nitrified by some living organism or bacteria.

The immense difference between the manurial value of the solid and liquid excrements of animals is shown in a striking manner in some of the recent experiments, and the analyses of the stable and farmyard manures which the investigators employed, showed that the effects of these manurial substances was plainly connected with the proportion of soluble and active nitrogenous matter which they contained. The original voidings of animals have a far greater manurial value than the final product of the manure heap which the farmer or gardener carries to his land. In the whole progress from the stable to the land the loss of nitrogen is going on, this loss falling on the most valuable constituent of the manure, and resulting finally in a residue of comparatively inert matter.

Maercker illustrates the loss of nitrogen in the ordinary preparation of farmyard manure as equal to forty-five pounds per fatting beast in one year. The data shows that when the quantity of organic matter applied to the soil exceeds a certain proportion, the conditions prevailing in the ground may be entirely changed, and a nitrifying medium converted for a time into a denitrifying one, the oxygen demanded by the large bulk of decomposing organic matter being in this case obtained by the destruction of the nitrates in the soil. An organic manure which is effective when applied in small quantity may thus become injurious when made use of in excess. This has also been found to be the case with the more soluble artificial manures. It is better to use small doses, frequently repeated, than large doses applied at [illegible] a very few times.

Harpenden. J. J. WILLIS.

THE GARDENERS' MAGAZINE, JANUARY 22, 1898.



BEGONIA WINTER CHEER. (Flowers rich carmine.)

TREE PRESERVATION IN SUBURBAN DISTRICTS.

IN the course of an important paper contributed by Mr. John Wilson, Leazes Park, Newcastle, to the "Transactions" of the English Arboricultural Society on the planting and management of town and surburban trees the author makes the following pertinent remarks with reference to tree preservation :—

In laying out suburban land for ordinary street purposes, it becomes no easy matter sometimes to save existing trees ; still, I am satisfied that, with reasonable care and consideration, much might be done toward their better protection and preservation. The general tenor of public opinion at the present time is in favour of preserving old trees whenever it is reasonably possible. In this matter, however, the same public opinion, it must be confessed, is often weak against personal interest, and is often also purposely withheld, probably on the principle that "what is everybody's business is nobody's business." Therefore things are often allowed to go on without any kind of protest, and a good deal of unnecessary destruction consequently takes place. I hold it to be the province of such a society as the English Arboricultural Society, to use its influence in order to support public sentiment in regard to such matters. This it ought to be able to do with a competent knowledge, and without any particular danger of being carried away by the fascination of hobby. Hobbies, it must be remembered, if not wisely tempered with consideration for others, are ever apt to carry their riders beyond the bounds of a reasonable limit ; and I have known an intemperate zeal for preserving old trees pushed to such a ridiculous extent as to almost warrant the epithet of folly. As an individual, I advocate every reasonable care in the preservation of old trees (and I wish the society to advocate it as well), but not to push the matter to extremes. It is remarkably easy to persons who have no monetary interests at stake, to point out how things can be done ; but how far will it prevail with those whose chief concern is pounds, shillings, and pence? The most that can reasonably be expected from them is that no wanton destruction shall be permitted to take place. Perhaps I might go a step further and appeal to the good sense of responsible workmen. I have often noticed with regret that when trees have been left standing they have frequently been sadly disfigured through sheer carelessness. Bark stripped off, branches broken and mutilated, roots hacked and bruised, and the whole tree so hopelessly damaged that it were better to have taken it down altogether. Instances such as these are the more regrettable when it is evident that a little care and common sense in the method of working might have preserved an object of beauty, and, perhaps, of considerable usefulness too.

It not unfrequently happens that when excavations are being made for buildings, some of the roots of the trees are unavoidably laid bare, and have to be cut away. This often affords a favourable opportunity to add some fresh material to the trees in order to induce the growth of fresh young fibres, which are ever the health-sustaining portion of the roots. A little extra care when chances like these offer would doubtless often save considerable trouble and expense afterwards to those immediately concerned and with ultimate satisfaction.

I have principally in view middle-class streets, and it remains for me to say a few words about the more pretentious streets. These always offer a much better field to the arboriculturist : more money, more influence, more space—in short, infinitely better opportunities of displaying a decorative taste. Even the builder himself has here a better chance to be merciful, and to "spare the tree," when the garden space is larger. Suburban villas, too, as a rule, afford good scope for the growing of fancy trees. Indeed, I often think towns are characteristic in their suburban planting. I judge not altogether from the main bulk of the trees planted, but rather from that love shown for having the rarer and more beautiful species dotted about. In some places, poplar, willow, sycamore, elder, privet, and such like, satisfy the paucity of arboricultural taste.

One thing I ought to mention here in reference to the preservation of old trees on new villa sites, that is, the great difficulty of adapting young and newly-planted trees to the old ones left standing, and at the same time having due regard to the general effect. It becomes a nice question of taste, and a good deal might be said about it which would be interesting to landscape gardeners, as well as to those more intimately concerned in the preservation of trees.

It must be admitted that tree planting, in and about large towns, has received a considerable impetus during recent years. Much, however, yet remains to be done in order to improve the methods of planting, and particularly in regard to the way the trees are afterwards cared for. Trees of more suitable quality require to be provided and planted, and, in many cases, more of them, so that a selection of only the best and most vigorous can afterwards be made. It is a remarkable fact that while certain trees, in a particular situation, at once start away and continue to thrive, others, under the same apparent conditions, languish and die, although the plants at the first were of the same quality, and had the same care bestowed upon them.

Where trees are transplanted favourably—that is, into better conditions—they much sooner overcome the effects of removal from the nursery ground than when transplanted unfavourably. Trees intended to be planted in towns should never be grossly grown in the nursery, but should always be of a firm, robust, and healthy constitution, and with plenty of fibrous roots, so that a good start, if possible, may be ensured to them in their new home. Richly and closely-grown trees always suffer most from removal, on account of their more attenuated character, both of roots and branches. They, no doubt, make the best appearance when so grown, and for that reason are more attractive to the inexperienced purchaser. Price and height—the common tests usually employed—are of themselves very inadequate standards to judge the qualities of trees by, and are never adopted by one who thoroughly knows what he is about. One is reminded of the story of the man who, having a house to sell, brought a brick with him to town in his pocket as a sample of the property.

When once young trees have been planted and become established, it is a very important matter indeed to know how to take care of them. There is, I regret to say, oftentimes far greater lack of judgment displayed in their after-management than at the first planting. I have frequently noticed, too, that many of those persons who have been most enthusiastic about tree-planting in towns take comparatively little interest in the matter afterwards. Now, if the peculiarities of human character were the subject of my disquisitions, I might follow up this as rather an interesting trait ; but dealing as I do with the subjects of planting and managing trees, I must not be tempted into by-paths likely to bring me into difficulties barren of arboricultural interest.

It is a noticeable fact that the generality of people take more delight in trees that are full-grown, than they do in young ones. This, I dare say, is quite a natural disposition. Old trees are more imposing—more taking—they afford both shade and shelter, and are infinitely less trouble. It is only the enthusiast that is interested in them at all stages of their growth. He alone watches their progress from year to year, and enters into a kind of companionship with them, and regards them as friends. I once heard the late Dr. Bruce say, that his venerable friend Mr. Clayton, of The Chesters, told him he did not like to cut down certain old trees, which the storms had shattered, because he and they had grown old together. This is the natural conservative spirit in an old man, for long-loved and familiar objects. A bond of sympathy even for old trees that, like their master, had baffled time, and, as it were, fought for immortality ; for it is a universal principle that everything struggles to be—that is, to endure on its own individual account. This, it may be said, is but sentiment. Perhaps it is so, but how are our grand old trees, picturesque and historic trees, going to be preserved without sentiment? I heartily wish that there were more genuine sentiment in favour of such grand and noble productions of the earth.

A sort of protracted murder (I can call it by no other name) is frequently perpetrated upon town trees under the plausible term, pruning. Among all the varied operations connected with arboricultural work, this appears to me the least intelligibly understood. Foresters may wrangle and argue about the best methods of securing the greatest amount of marketable timber at the least possible cost. I shall not meddle with that ; it is a money-making job, and outside of my legitimate domain. With regard to ornamental trees, however, or trees planted for ornamental purposes, I do claim, according to charter, so to speak, the right to say a few words. There is plenty of room for dispute with regard to the consistency of many of the practices that come under the name of management. Management, as applied to ornamental trees, may be regarded as a kind of professional interference with the ways of Nature, in order to bring about a result in some way consistent with the adopted ideas of the "professor" himself. However, though we may admire Nature fervently, we do not choose that she should have unqualified liberty to disport herself in vagrant freedom about our dwellings. According to the peculiar dictates of his fancy, man seeks to subject the joyous liberty of Nature to his prosaic convenience. If he be a person endowed with a well-balanced judgment, and has withal a cultivated taste, he will never coerce his trees beyond what more important considerations require. The object chiefly in view when planting ornamental trees is that they may grow and display some characteristic beauty. Now, beauty in a tree is not confined to any special form, but each kind assumes a general shape peculiar to its tribe, which is always more or less pleasing as it approximates a perfect type. To be periodically hacking trees into shapes unnatural to them, common sense might induce people to see was absolutely wrong ; yet this is what is constantly taking place under a mistaken idea of pruning. Pruning, in its proper sense, is not, surely, to ruthlessly denude a tree of a lot of its healthy branches, but to train, thin, and regulate them with considerate care, with due regard always to the character and well-being of the tree itself. Why young trees intended for picturesque effect about a lawn should be trimmed into poles, with a tuft of branches at the top, I can never quite understand. Things of beauty are altogether out of the question. It never seems to enter the heads of those practitioners that, in addition to making a thing that is hideous, they are at the same time mincing away the vital energy of the plant itself, and helping every adverse element to bring about its ultimate destruction. I have often noticed, too, certain shrubs and bushes that have been persistently cut down, gradually, after few years, to give up the ghost, and "pass into nothingness." It seems to me that if trees were "protected" against this kind of unnatural treatment, a great and important point would be gained, and there would be vastly fewer sickly, hide-bound specimens disgracing our suburban gardens and public pleasure grounds. The same physiological principle holds goods in regard to roots. Where annual digging is practised, great quantities of young fibrous roots are constantly being destroyed, which still further debilitates the struggling tree.

When trees have outgrown reasonable bounds, however, and it has become necessary to curtail them, it should always be done carefully, and with well sharpened tools. Every competent arboriculturist knows that it is seldom required to cut off large branches from growing trees, but that they can be reduced by judicious "shortening back," as it is called, and with little or no disfigurement to the tree itself. In "shortening back," the cuts should always be made clean, as these heal up much more readily than when the operation is roughly performed. Besides, it betrays a peculiar kind of negligence and want of skill when long tongues of bark are left protruding from the sides of the cuts. Even where large branches are to be taken off by the saw, it is always advisable to smooth the surface of the saw-cut with some edge-tool. This prevents the damp from hanging upon the rough surface and causing decay. Indeed, as a further means of preservation, it is a commendable plan to paint any large cut carefully over ; and this is almost always done by skilful workmen.

It is always very important that newly-planted specimen trees should be staked or stayed in some way, in order to prevent them from being knocked about by the wind. More particularly ought this to be attended to in regard to trees planted on the sides of streets. The common practice is to tie them to one strong stake, which should be proportioned to the height of the tree. A watchful eye should be kept on the ties, so that they be kept secure, and no damage done by their cutting into the bark. A good plan of supporting trees, and consequently a means of protection, is, that instead of a single post-like stake, to have three, or even four, lighter ones placed round the stem, but not too close to the bottom. These will be brought together at the tops and secured, along with the stem of the tree, and a little wrapping of some kind should be put round, in order to protect the bark against friction. It is not advisable to have the supports too rigid ; they will be all the better in giving a little to the strong winds, so long as they have sufficient elasticity to recover themselves from the strain. No doubt this latter method will, in the first instance, be a little more trouble and expense, but it will be sufficiently compensated by the efficacy of the work when it is once done.

As to the general management of common trees, planted principally for ornament, there is really not much to be said. The leading points are tolerably well understood by all experienced men. Local circumstances, no doubt, often play an important part, which is inexplicable to science ; and which renders it not always wise to dogmatically denounce rule-of-thumb experience. Indeed, it would seem both prudent and profitable to keep in friendly touch with common every-day methods. They will certainly not square at all points with the technical formulas laid down in the school ; but where satisfactory results stand out in evident contradiction to authorised rule (which not unfrequently happens among cultivated trees), there is something for science to investigate *à posteriori*, as a schoolman might say, and to establish a definable connection between cause and effect.

"THE PLAY'S THE THING."—This has often been echoed by all sorts and conditions of men since the time when Shakespeare made it historical through the medium of Hamlet. The play holds the mirror up to nature, and shows us that men may be influenced by good to evil. It proves, in fact, the truth of the saying, "All the World's a Stage." Holloway's Pills and Ointment have for many years played a leading part in the drama of life. They have long been a source of relief and cure for most known complaints in all parts of the civilised world. Adults and children are alike benefited by these wonderful remedies, as they are suitable for the weakest as well as the strongest constitutions.—[ADVT.]

WORK FOR THE WEEK.

COOL ORCHIDS.

THE temperature of the odontoglossum house at this season of the year at dusk should be about 50 degrees, falling two or three degrees by the morning. During severe frost, or in very cold windy weather, the temperature may be with safety allowed to fall to 45 degrees at night. It is advisable, however, in such weather to cover the lower portion of the roof, where the plants are near the glass, with mats, these coverings being removed in the morning as soon as it is light and immediately the temperature commences to rise. The day temperature should be several degrees above the figures indicated. Damping should be done, if necessary, in the morning when the house has reached its maximum temperature; a little bottom air should also be afforded, passing between the hot-water pipes before coming into contact with the plants. In mild weather, such as we are having now, we keep a little bottom air on the odontoglossum house both day and night. Imported plants of Odontoglossum crispum should be potted in equal parts of peat and fresh sphagnum moss. I find it best to pot them in comparatively small pots, as they then become established quickly and are more readily managed. The pots should be three parts filled with clean crocks and charcoal, and the specimens should be made firm in the compost by the use of small wooden pegs, allowing a space between the leading pseudo-bulbs and the rim of the pot sufficient for the development of the following year's growth. Great care should be taken in watering these until they become established; they should be sprayed over on bright days to help plump up the bulbs.

Sophronitis grandiflora, a native of the Organ Mountains of Brazil, will be making a grand show in the cool house at the present time. It is a very handsome orchid, its large and beautiful flowers lasting six weeks or more in perfection. This species thrives best on blocks of wood or in shallow pans suspended from the roof in the warmest end of the house; it delights in shade, and should never be exposed to bright sunshine. If pans are used they should be three-parts filled with clean crocks and charcoal, the compost consisting of sound fibrous peat and fresh sphagnum moss in equal parts; this may have a slight rise to the centre of the pan, but great care should be taken to make the specimens firm, so that they will not be moved out of position when taken down for watering. While growing they should never be allowed to become dry, and if kept in a moist atmosphere and free from insects they will thrive. Masdevallia tovarensis is a very distinct and beautiful orchid, its pretty, sweet-scented, white flowers, generally produced in pairs, being invaluable for many decorative purposes; the plant moreover lasts a long time in flower. Care should be taken in watering the species at this time of the year, and a watchful eye should be kept for thrip, which if allowed to accumulate, will soon disfigure the foliage, and cause the plants to dwindle away. Wash the foliage with XL All liquid insecticide, when the first trace of thrip is seen, but even this must not be used too strong. Use the insecticide at the rate of one wine glassfull to a gallon of clean, soft water.—G. SHILL, *New Hall Hey Gardens.*

STOVE PLANTS.

No time should be lost in obtaining and placing under cover a supply of good fibrous turf, leaf-soil, and burnt refuse, so that there may always be plenty of material in the right condition for potting and other purposes whenever necessary. Look to the stocks of peat, bones, patent manures, and other requisites for the successful cultivation of stove plants, and order in sufficient to replace any deficiencies, so that there may be nothing to hinder potting operations when the various subjects come under hand. A few bags of cocoa-nut fibre refuse will be found very useful for mixing in the soil for propagating purposes, also for starting such subjects as caladiums, achimenes, gloxinias, &c.

As their bracts become fully developed, poinsettias should be removed to a house where a temperature of 55 degrees is maintained, and where there is less humidity in the atmosphere than it is necessary to maintain in the stove. Do not starve them, but continue to afford water until their beauty has passed, after which they may be stored in a dry corner in a house where the temperature does not fall below 50 degrees. The same remarks apply to Euphorbia jacquiniæflora, with the exception that when flowering is over it must not be dried off to the same extent as the poinsettia. Thyrsacanthus rutilans is now throwing out its racemes, and the pots should be stood on others inverted, or be slung to the roof by means of wire, as in this way they show off their long pendulous racemes of scarlet flowers to perfection. Under good treatment these racemes will hang from six inches to a foot below the bottom of the pot. Begonias, such as B. manicata, B. hydrocotylifolia, B. heracleifolia nigricans, B. nitida, B. coralina, B. hybrida multiflora, B. Knowslyana, and others, are advancing rapidly towards flowering, and should all receive liberal support from stimulants. If these have to be afforded a place in the stove, then put them where they will not be syringed. A few tubers of gloxineas and achimenes should now be started to afford an early supply of flowers. A good plan in starting gloxinias is to shake them free of old soil, and pack them fairly close together in a cutting box, placing below them and between the tubers a mixture of one part loam to one each of cocoanut-fibre and leaf-soil, with a good addition of sand and powdered charcoal.

Keep the stove proper at a temperature of 60 to 65 degrees at night, allowing a rise of five degrees by day from fire heat. Should there be a difficulty in keeping up the requisite temperature, rather than get the pipes excessively hot in attempting to do so, be content with a few degrees less, and keep the atmosphere dryer. The intermediate house may range five to eight degrees cooler. Afford all foliage plants a thorough syringing at least once a day, preferably about noon; towards dusk damp well amongst the pots, and on the paths; and if the house is apt to dry quickly the man on duty should damp down thoroughly again when he goes round his fires the last thing at night.—J. TUNNINGTON, *Ripley Castle Gardens.*

KITCHEN GARDEN.

WHENEVER the weather is favourable, and the soil in a suitable condition for working, a sowing of peas may be made in the open quarters. We have long since discarded the old round-seeded varieties, as there are now so many of the marrow type of superior quality that are quite as early and as productive. These marrow kinds are, however, more subject to rot if sown so early on cold, wet soil, unless some protection be taken to ward off the heavy rains. It is, therefore, by far the best plan to defer the digging of such ground until the time of sowing, and then cover the rows to prevent the rains from beating the ground down again. Germination is slow at this time of the year, so that the young plants will not show themselves through the soil for at least three weeks, by which time there will be a prospect of the weather becoming a little warmer. Those who can afford room to make a sowing under glass should do so, as peas may be gathered from such a fortnight earlier than from those sown in the open at the same date. It is not actually necessary that soil be attached to the roots at the time of planting; though if it can be retained it will prevent the plants receiving any check should the weather be unfavourable. If sown in boxes, from six to seven inches deep, there should be no difficulty in transferring the plants to the open quarters without disturbing the roots to any serious extent, but there is more satisfaction in sowing them in pots, as these are more portable, and can be readily moved should occasion require. A sowing of broad beans should now be made, choosing some of the long pod varieties, as these are more productive than the Mazagan. There are now several green forms of these that are very good, and of fine flavour when cooked. They should have preference to the older forms. Where these are desired extra early sowings should be made in boxes for transplanting, as such will be found very serviceable. Broccoli have been turning in very rapidly of late, so much so that many of the early kinds will be over before their usual time. That fine variety, Snow's White, has been unusually good this season. As soon as any show signs of turning in, protection should be afforded them, as otherwise should a sharp frost visit us they will be spoiled. Green vegetables of all kinds have been very plentiful up to the present time, so that there has not been such a demand for roots. Pay special attention to the sowing of small seeds, such as mustard and cress, not putting in more at one time than will suffice for a supply; small and frequent sowings are the most serviceable. Often, too, small celery is required in the kitchen, so that frequent sowings of this should be made.

Where mushrooms are grown in large quantities the manure for making the beds must receive proper attention by being frequently turned over, until such time as a sufficient bulk has been brought together to make up the beds. There are but few places where sufficient accommodation is provided for the preparation of the various things necessary to maintain a constant supply of all kinds of vegetables, and ample shed room is one of the things lacking in most gardens. Where sufficient of these useful places are provided, there are many subjects that could be stored in them both in summer and winter to great advantage. It is not altogether the frost that destroys our vegetable crops, for often they suffer as much from damp as anything else. Open sheds are therefore very useful for storing endive, broccoli, lettuce, and others of like nature that suffer in this way. They are also of value in summer, particularly when facing north, for retarding, and for mushroom culture. Those possessing such accommodation would do well to utilise it for the protection of broccoli that are just turning in, for if these are taken up with a ball of earth attached and laid in, they will receive but little harm. This is by far a better mode of protection than hanging them up, as this causes the flavour to deteriorate sadly. Never cover the foliage unless there is actual danger of the hearts being spoiled by frost. Whenever the weather is unfavourable for outdoor operations, examine the roots in the store-house, and, where the supplies of any of them, such as artichokes and turnips, are likely to run short, sufficient should be put under cover for use, in case we should have frost to prevent those in the open ground from being lifted, but, as all such vegetables are sweeter when used fresh from the ground, no more should be housed than is necessary to keep up a supply. Onions in lofts and seed potatos should also be looked over, and any that are found decayed removed. It is by timely attention to these things that much annoyance is often averted. A good quantity of suitable labels should also be made, in order that, when the seeds are sown or planted, they may be properly named.—H C. PRINSEP, *Buxted Park Gardens.*

FRUITS UNDER GLASS.

PEACHES already started may be kept well moistened overhead with the syringe daily; borders and paths, too, should be freely damped down to produce the partially-saturated atmosphere which is conducive to a good start. Trees already in flower should be kept rather dry as regards top growth, and a daily visit to the house just before noon should be paid to give the trees and trellis sundry smart taps with the hand to free the pollen, and this should be sufficient attention in the matter if the blossom is plentiful and vigorous. If, on the other hand, flowers are scarce and not robust, it would be wise to go over each one and brush the anthers and pistils with a camel-hair brush or a hare's foot. Keep a fair amount of heat in the pipes, especially during the early part of the day, and ventilate daily, little or much, in accordance with the weather. Late trees should be pruned and tied forthwith, and another thing that must not be neglected is to see that the border is in a satisfactory state as regards water. My opinion is that more bud-dropping is caused by letting the trees go through the winter months in too dry a state at the roots than from all other causes whatsoever. Some varieties are especially prone to bud-dropping, but it may be induced in all by drought; and my advice is that, if there is any doubt about the matter, the borders shall be thoroughly soaked forthwith. Mulching, too, should not be neglected, especially in those houses where the borders are trodden on throughout the growing season, but, before mulching, all cleansing operations should be finished. Insecticides and tree washes are so numerous and so good that one need not particularise, but, whatever is tried, it should be used in accordance with the vendor's directions, or, if any variation be permitted, it should be on the side of weakness, especially in case of mild weather and forward buds. Houses in work should have a minimum temperature of 50 degrees, and the usual rise with sun heat

With lengthening days strawberry forcing will become an easy matter provided proper care is taken to keep the plants well up to the light and to afford plenty of room for those in flower. The temperature for batches just moving should be the same as recommended for peaches, those which are in flower may be kept from five to ten degrees warmer; early flowers should be carefully fertilised with the camel-hair brush so that there shall be a sufficient set from the earliest and strongest flowers on each plant. Batches just brought under cover should be allowed to commence growth before they are fumigated or dipped, as the few days thus spent in a genial temperature will wake up any dormant insects and hatch eggs that would escape destruction if the work was done at the time the plants were brought in. Where working vineries are the only available places for strawberry forcing the plants should be thoroughly syringed daily, except when they are in flower, and again when the fruits are ripening, as it is only in this way that it is possible to prevent an attack of red spider that would eventually injure the vines. Strawberries should always be kept well watered from the time of starting until the fruits are ripening, and any neglect of this simple matter will be fatal to the prospects of a good crop.

Any grapes which may still be hanging should be cut at once and bottled, so that the vines may be pruned before there is any chance of their bleeding. Even the use of styptic will not avert bleeding if the sap has begun to rise, and there is absolutely no reason for deferring the cutting of grapes to so late a date. I have at the present time a considerable number of Muscat of Alexandria bunches in perfect condition that were cut and bottled before the end of September, and both berries and stems are as plump as on the day they were cut. After pruning the vines, clean and suspend them at once, then remove the top inch or two of the border and replace with new soil. Melon seeds may now be sown and the young plants will probably overtake those sown earlier, besides being stronger; sow two seeds in a three-inch pot of loamy soil, and remove the weakest if both germinate. The soil for sowing should be moist enough to induce germination without any watering further than a light spraying with the syringe now and then before the young plants appear. Plunge the pots in bottom heat as near the glass as may be in a house with a minimum temperature of 65 degrees; cover with a sheet of glass until the plants are well above the soil.—J. C. TALLACK, *Livermere Park Gardens.*

AN EXPERIMENT IN ELECTRICAL PLANT-CULTURE.

PROFESSOR L. H. BAILEY, of Cornell University has, Mr. Theodore Waters states in the *Westminster Gazette*, been asked to go to Finland to conduct a series of experiments in electrical plant-growing, in conjunction with Professor Lemstrom, of the University of Helsingfors. The experiments to be carried on have nothing to do with the electric light, or the running of electric wires through the soil for the purpose of forcing the growth of plants by direct current stimulation. They are to be based on some pertinent observations made by Lemstrom, of the effect of the aurora borealis on the plant growth of the north.

It is a well-known fact, as Mr. Waters observes, that the plants of the north arrive at maturity in a much shorter period of time than those plants which are grown further south. It is necessary that these plants should arrive at maturity very quickly, inasmuch as the summer season in the north is very brief, and it has always been looked upon as a wise provision of Providence that the plants were enabled to accomplish their business in life in so short a space of time. Professor Lemstrom, however, casting aside the providential idea, states that the rapid growth of plants in the far north is due directly to the light of the aurora borealis. Light is one of the necessary natural agents in promoting plant growth, and the efficacy of continuing the day-light by substituting in its place electric light for the purpose of increasing the number of "growing hours" of plants has already been proved. In addition to the fact that the light of the aurora might tend to increase the number of growing hours of plants of the north, Lemstrom contends that they are also stimulated by the presence of the large amount of atmospheric electricity, to which, as it is contended, the presence of the aurora is due.

Lemstrom, in furtherance of his ideas, has been carrying on a series of experiments in which plants have been subjected to atmospheric electricity. But these experiments, while in a measure thorough, have not been carried out on a sufficiently extended scale to warrant any large assumptions being made in the matter. It is Lemstrom's idea that in conjunction with Professor Bailey some very important work can be carried on, and it is for this purpose that Professor Bailey is making ready to proceed to Finland.

If the plans of the two experimenters are carried out in the manner which is now contemplated, the result will be an electric farm of a decidedly picturesque character. It is proposed to erect a line of posts around this farm or field in which the experiments are to be carried out. From post to post, through the air above the ground, wires will be stretched, and at convenient distances along these wires small knobs or points will project. A static current, such as produced by the Holtz machine, will be sent over the wires, and will be allowed to jump across the open space between the wires from one point or knob to another. A constant flow of elecricity through the air will thus be accomplished, and the surrounding atmosphere will be, in a measure, saturated with the current. At least, this is the idea of the experimenters; certainly at night the scene should be very picturesque. The tiny points of flame jumping from wire to wire, from knob to knob, in the background of darkness, ought to create a picture such as might be thought to exist only in the fabled farms of fairyland. Professor Bailey, in speaking of the scheme, says:—

"Our contemplated experiments point to the application of atmospheric electricity to the growing of plants. Lemstrom and myself have devised a scheme by which we are to work in unison, some work to be carried on in Finland, and some to be carried on in America. He has recently suggested that I should go to Finland in order to look over his experiments, and to be better able to undertake them here. Lemstrom was first led to consider this whole subject by observing the influence of the aurora on the atmosphere and plant-growing, and thought that the electrification of the atmosphere had a great deal to do with the growth in the Arctic regions. He went to Spitzbergen for the purpose of investigating the electrical phenomena and the meteorology of plant-growing.

"I have recently pointed out to the members of the Massachusetts Horticultural Society the great effect which atmospheric electricity has on the growth of plants. Atmospheric electricity exerts a very powerful influence upon vegetation. The experiments of Grandeau were designed to determine this point. Plants were grown in the free atmosphere which is always in a greater or less state of electrification, and also in a wire cage from which the atmospheric electricity was excluded. Maize in the free air was in every way better than the other, not only in the bulk of all its parts, but in the amount of ash, and of both nitrogenous and non-nitrogenous matters. Grandeau found that plants deprived of the influence of atmospheric electricity have in the same length of time given 50 to 70 per cent. less bulk and 50 to 60 per cent. less fruit and seeds than plants subjected to normal conditions, that is, those to which atmospheric electricity had free access. Celi shortly afterwards reached similar results. So did Leclerc. But by far the best investigations upon the electrification of the atmosphere in reference to plant-growing were those made in Finland and in France by Lemstrom, physicist in the University of Helsingfors.

"Lemstrom was first led to his inquiries by observations upon vegetation and meteorological phenomena in the high North, particularly in Finnish Lapland and Spitzbergen, when he came to the conclusion that much of the rapidity of vegetation in the short summers is due to climatic electricity. His first experiments were made in the laboratory, and the results were so promising that he at once turned his attention to the field. He made an experiment on a small field of barley in Finland. One portion of the field was covered with small parallel wires a metre apart, and secured to porcelain insulators which were secured to small posts on the margin of the field. At intervals of a half-metre each wire was furnished with a metal point, from which the current could discharge into the atmosphere. These wires were connected to the positive pole of a four-disc Holtz machine, which supplied the current. The current was supplied from the middle of June to September 1, from six to ten o'clock in the morning, and from five to nine in the evening. The barley was well up when the experiment began. The harvest showed that the electric plot was over thirty-five per cent. ahead of the remainder of the field, and the yield and the quality of the grain was improved.

"Having determined the good effects of atmospheric electricity in high latitudes, Lemstrom now carried his experiments into France. Here he treated cereals, garden vegetables, and a variety of fruits. The result was equally good in the warm country. But although these experiments of Lemstrom have shown that the application of electricity to the atmosphere generally influences plants profoundly, and is usually beneficial, we are yet uncertain as to how this effect is brought about. It is highly probable, however, as Lemstrom thinks, that the modification is not the direct result of the electrification of the plant itself, nor the atmosphere, but that they follow some chemical change in the atmosphere which is engendered by the current. This is one of the problems we will attack while working in unison. If it is solved we shall probably know better how far to go with this artificial plant-stimulating process. In some cases it is found that stimulation is advisable up to a certain point, but from that point onward it becomes injurious. If we can reduce the system to a practical basis, our forthcoming experiments and those of the past will not be or have been in vain."

NEW BOOKS.

The Rosarian's Year Book for 1898. Price 1s. Edited by the Rev. H. H. D'OMBRAIN. (Bemrose and Sons, Limited, 23, Old Bailey, London.)—This highly popular annual is, as usual, remarkable for the interest and usefulness of its contents, and will not be less heartily welcomed than have been the many previous issues. An excellent portrait of our esteemed coadjutor, the Rev. J. H. Pemberton, forms the frontispiece, and in the opening remarks to his appreciative sketch of the work of this distinguished rosarian, the editor observes: "There are few notabilities in the rose world who are better known than the indefatigable and energetic clergyman whose portrait is given in this issue of the 'Year Book,' and certainly no one whose judgment is more appreciated from his intimate knowledge of the flower he so successfully cultivates. He has been a loyal and constant supporter of the society ever since its foundation, having exhibited at all its shows, and always more or less successfully, and if anybody can be an amateur in the truest sense of the word it is Mr. Pemberton. Everything that is done in the rose garden, with the exception of digging and hoeing, is done by himself and his energetic sister, whose portrait, I think, ought to have been placed with his. He has doubtless some advantages on his side. He inherits the love of roses from his father, who taught him how to bud, &c., when quite a lad; moreover, he resides in the house where his father and grandfather lived, and, above all, he has the constant assistance of his excellent sister, whom nothing seems to daunt or tire. There can be no doubt that anyone who can do all the work necessary in the rose garden has a great advantage over those who are obliged to employ paid labour. He knows where to look for his roses on the evening before the exhibition, and, as he has been watching their development some time before, has not to waste any time looking for them. Mr. Pemberton commenced rose showing in 1874, when he took a first prize at a local show. He exhibited at the first show of the National at St. James' Hall in the class for twelve distinct varieties, obtaining the second prize out of forty exhibitors, and never since that has he been absent from an exhibition of the National, either metropolitan or provincial. In 1885 he felt sufficiently strong to exhibit in the Trophy Class, and gained the first place. In this class he has exhibited ever since with the exception of one year, 1888, when he had not sufficient flowers in bloom, and he has gained the Challenge Trophy three times, been placed second six times, and third three times, but never out of it altogether. He also staged for the Jubilee Trophy nine times, gaining it four times, being placed second three times, and third once." The more important papers in the issue are: "Yellow Roses," by the Rev. A. Foster-Melliar, who, in the course of his interesting communication, describes Maréchal Niel as "the finest yellow rose known by a long way"; "A Chat about Rose Sports," by Mr. A. Piper; "Roses in the South-west of Scotland," by the Rev. D. R. Williamson, who states that "though many of the roses of continental origin succeed admirably in Scotland, I have come to the conclusion that those which have hitherto been most successfully cultivated are of British origin"; and the "Abolition of the Trebles," by Mr. George Paul, to which we referred in our issue of the 8th inst. Miss Muriel Grahame contributes a chatty little paper on rose shows; the editor gives a sketch of the work of the National Rose Society in 1897; and Mr. E. Mawley discusses the weather of the rose year, the latter being described as "really good."

Gardening Year Book and Gardening Oracle for 1898. Price 1s. By the EDITOR of the GARDENERS' MAGAZINE. (E. W. Allen, 4, Ave Maria Lane, E.C.)—The Gardening Year Book is so well known and highly appreciated in horticultural circles as to render it unnecessary that we should do more than record the publication of the edition for the current year, and briefly indicate its contents. It is with satisfaction we do this, for the work has now reached its fortieth year, and enjoys a higher degree of popularity than at any other period in its long life. In this respect it occupies a perfectly unique position, and there can be no doubt that the estimation in which the work is held is largely due to the recognition by the editor of the importance of both freshness and utility, and the consequent provision of matter specially written for each issue, and adapted to the continuous changes in the fashion of horticulture. Diary pages are, as usual, provided for keeping of a brief record of garden work, and the almanack pages contain a series of short reminders, which both amateurs and professionals assure us are found extremely useful. Full directions are given for the management of every department of the garden, outside and under glass, throughout the year, and concise directions are given for the successful cultivation of all the plants, flowers, fruits, and vegetables generally grown, and accompanying the cultural directions are selections of the most useful varieties. The new plants, fruits, flowers, and vegetables introduced during the past year are briefly described, and illustrations given of some of the more important introductions. The most destructive of the insect pests are figured and described, and the best means of keeping them in check pointed out. The recipes likely to prove useful in the garden have been extended and improved, and the lists of horticultural societies, and public gardens have been thoroughly revised to ensure accuracy. In addition to these features a mass of statistical and other information relating to the garden is given, and there are two coloured plates and numerous illustrations in black and white.

Vinton's Agricultural Almanack for 1898. Price 6d. (Vinton and Co., Limited, 9, New Bridge Street, Ludgate Circus, E.C.)—This publication, so long popular with agriculturists, continues to preserve as its chief features very extensive and carefully prepared lists of statistics, official information, societies, breeders' tables, fairs, &c., which render it helpful for reference. The statistics include the prices at the London Christmas Market, and the Imperial Corn Averages for December 11. About seventy large pages are devoted to tabular and official information relating to agriculture and stockbreeding. This edition contains, as in the case of previous issues, numerous special articles, chief amomg them being: Mr. Clare Sewell Read on "Reminiscences of Farming"; Mr. M'Connell on "The Dairy Trade"; Professor Wrightson on "German F Experiments"; Mr. William E. Bear on "The Royal Commission on Agriculture"; Mr. R. E. Turnbull on "Wheat Farming in England"; Professor Malden on "Digging"; Mr. Gilbert Murray on "Cross-bred Sheep"; Mr. W. Parlour on "As Others See Us"; Mr. Wm. Earley on "Improved Onion Culture." The illustrations comprise portraits of some of the leading agriculturists, and of several of the higher types of live stock. The portraits of agriculturists include Earl Spencer, K.G., president of R.A.S.E., Mr. Clare Sewell Read, Sir Cuthbert Quilter, Bart., M.P., Professor McFadyean; and three generations of the Sutton family.

My Garden Diary for 1898. Price 1s. (Sutton and Sons, Reading.)—An elegantly printed brochure containing well-arranged diary pages, and reminders of work to be done in each month of the year.

Hardy Perennials and Old-fashioned Garden Flowers. By JOHN WO (L. Upcott Gill, 170, Strand, W.C.)—In the publication of this manual we have a further proof of the popularity of hardy border plants and of an increased for information on their cultivation. The author, who has long devoted special attention to the cultivation of hardy perennials, tells us in the admirably-written preface to his work that "its object is not to give scientific information, but to furnish the names and descriptions of really useful and reliable hardy perennial plants suitable for all kinds of flower gardens, together with cultural hints on each plant." This object the book has fully accomplished, for within its pages some three or four hundred of the more beautiful species are enumerated and described and their cultural peculiarities fully discussed. The course of procedure adopted by the author has much to recommend it, for the amateur, in a careful perusal of the work, can have but little difficulty in making a selection adapted to his garden and taste, and having selected the species it is intended to plant, he can readily find all the information that could possibly be desired with regard to cultivation. Every detail essential to success is fully described, and with remarkable clearness, the latter being a point of considerable importance to those who have had but little experience in hardy plant culture. The plants are arranged alphabetically in the body of the work, and to still further facilitate reference to them there are two indices, in one of which the plants are arranged in alphabetical order, and the other they are grouped according to their colours. A few plants are not mentioned which we expected to find, and it is interesting to observe that while reference is made to the Chinese and Japanese chrysanthemums the hardy and free-flowering Chrysanthemum maximum and C. pallens are wholly omitted. The selection of early-flowering chrysanthemums at page 61 consists chiefly of generally-grown varieties; but it might be materially improved. Michaelmas daisies are briefly dismissed, for very few are mentioned, and of these two only are described; the selection of these useful hardy flowers should be extended in the next edition, and fuller particulars given with regard to the habit of the plants and the colour of the flowers. In the matter of nomenclature Mr. Wood has ignored the authorities and employed capitals in the specific as well as in the generic names without reference to their derivation. The use of capitals in this way does not impair the practical utility of the work, but as correctness is desirable in this as in other matters, they should have been avoided. Apart from this, the book is so thoroughly sound that we can strongly recommend it to those of our readers who are desirous of obtaining the fullest information on the most beautiful of the hardy plants that have been introduced to British gardens.

LAW.

ORCHID SALE.

THE case of ASHWORTH V. WELLS, heard in the Court of Queen's Bench on the 18th inst., before Mr. Justice Day and Mr. Justice Lawrence. This was an appeal from the Manchester County Court. The facts were these: The plaintiff, an amateur orchid-grower, had bought an orchid at a sale of the defendant's collection of orchids by Messrs. Protheroe and Morris on June 26 and 27, 1895. The orchid was warranted by the defendant to be a Cattleya Acklandiæ alba, a great rarity, if not unique. It had never flowered while in possession of the defendant, and it turned out after two years' cultivation by the plaintiff to be not an alba or white variety of Cattleya Acklandiæ, but the ordinary purple form, which was only worth 7s. 6d. The plaintiff then brought an action for damages. The defendant admitted liability and paid into Court twenty guineas and two guineas for interest, which he said was sufficient. The County Court Judge thought that the sum paid in was enough, and gave judgment for the defendant. He also found that if the orchid had really been an alba it would have been worth more than £50 at the time of the sale.

Mr. C. A. Russell, Q.C., who appeared for the plaintiff, said that the County Court Judge was wrong in thinking that enough had been paid into Court. He practically had only given back to the plaintiff the amount he had paid. He should have considered the value at which the orchid would have arrived at by this time. The claim was reduced to £50 in order to give jurisdiction to the County Court to try the case.

Mr. Montague Lush, who appeared for the defendant, said that as the sale of the orchid had taken place at a largely-attended auction the price given was the real market price. It was wrong to assume that if the orchid had been a white one it would have flowered by this time. It might never have flowered at all. On the question of measure of damages he cited several cases, and contended that the claim by the plaintiff was speculative, as no one had ever seen a white orchid of this class.

The Court held that the matter must go back to the County Court Judge, and Mr. Justice Day said he had come to this conclusion with considerable reluctance. He thought that the plaintiff's real cause of complaint was that he had had to pay the costs of the County Court action. The defendant admitted that he was wrong in his warranty. The plaintiff had spent time and trouble and money in cultivating the cattleya. The Judge of the County Court had apparently considered nothing but the original price of twenty guineas. It was very likely that if the orchid had been a white orchid it might have been worth more than £50, but it was only speculation after all, because such a thing as a white orchid of this particular species was really unknown. The matter should go back to the County Court Judge. Mr. Justice Lawrance said he did not disagree with his learned brother in sending the case back, though he thought that the Court had sufficient material to decide the case themselves. The true measure of damages was not the difference between the contract price of the orchid and the price at which it would sell now; but, putting it generally, the measure was the difference in value of the thing sold with the defect warranted against and the value of the thing without the defect. Here the evidence was all one way. If the orchid had been what it was represented it would have been worth perhaps £100. If the County Court had jurisdiction to deal with that amount the plaintiff might recover the difference.

EXHIBITIONS AND MEETINGS.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE annual meeting of this useful and ably-managed charity was held on Thursday, January 20, at Simpson's, 101, Strand. There was a fair attendance, and Mr. Harry J. Veitch, presided. After the usual preliminaries, the secretary, Mr. G. J. Ingram, read the report for the year 1897.

COMMITTEE'S REPORT.

It affords the committee much satisfaction to submit their annual report for the year 1897, together with an audited statement of accounts, and in doing so they are thankful to be able to record the continued prosperity of the institution, and its increased benefit to those old and needy people in whose behalf it was founded. With great pleasure the committee have to report that the fifty-eighth anniversary festival dinner in aid of the funds, held in May last, was most successful, and they desire to express their gratitude to the Right Hon. Lord Rothschild for so kindly occupying the chair on that occasion. They would also gratefully acknowledge their indebtedness to those gentlemen who so kindly served as stewards, to those who sent flowers and fruit, and to other friends who in any way assisted in making the festival a complete success.

During the past year nineteen pensioners have died, seven of them leaving widows, of whom five whose cases on being carefully investigated and found to be in every way satisfactory, have been placed on the pension list at £16 a year in succession to their late husbands in accordance with Rule III., 13. The committee have now the pleasure to announce that they have decided to add nineteen additional pensioners to the number at present on the funds, ten of whom, having been accepted under Rule III., 5, they recommend the subscribers to place on the pension list without the trouble and expense of an election; the remaining nine to be elected by vote from the approved list of candidates in the usual way. This addition will make the total of pensioners one hundred and sixty seven, the largest number of beneficiaries receiving permament aid since the foundation of the institution. Yet there will be thirty-five unsuccessful candidates who will perforce have to wait for that assistance which they so much need. The committee sincerely wish it were possible for them to render aid to the larger number, but with the financial responsibility to those now on the funds, which it is impossible to accurately calculate, they do not feel in a position to recommend a greater increase in the annual expenditure, than that entailed by the addition of the number already stated. In the past year there have been held in aid of the charity an amateur operatic performance at St. George's Hall, kindly organised by Mr. H. Morgan Veitch; a flower and fruit stall at Richmond Horticultural Exhibition, kindly arranged by Mrs. Algernon Chancellor; garden fêtes at Reigate and other places; concerts at Altrincham, and various other functions in different parts of the country, to the promoters of which, one and all, the committee tender their very hearty and sincere thanks. They would also gratefully recognise the self-denying labours of the hon. secretaries of the several auxiliaries, which are still attended with marked success, and are the means of creating an ever-widening interest in the good work of the institution.

It will be remembered that the committee at the last general meeting suggested the sending to each unsuccessful candidate at the 1897 election, the sum of £5 on June 21, in honour of the Diamond Jubilee of her Majesty the Queen. This they are happy to say was done, and the grateful letters of acknowledgment received from the recipients showed how greatly appreciated were the welcome and, in many cases, timely gifts. The committee likewise announced that they had inaugurated a fund to commemorate the long and beneficent reign of our beloved Queen, the patroness of this charity. This fund, by her Majesty's gracious permission, is called the "Victorian Era Fund." They are now gratified beyond measure to state that the appeal issued in its behalf was most generously responded to, the sum of £4,075 being received, which amount has been invested in the names of the trustees in the Great Western Railway 5 per Cent. Guaranteed Consolidated Stock, and the interest derived therefrom will be annually divided pro râta among those unsuccessful candidates who formerly were subscribers to the institution, in order to render them some temporary assistance while waiting election; no candidate to receive more than £10 in any one year. The committee would like to mention the names of all who have so liberally and kindly contributed to this special object; but, whilst gratefully thanking all who did so, they hope it may not seem invidious if they particularise a few generous and munificent donors who greatly helped to secure the substantial amount raised: His Grace the Duke of Westminster, Lord Rothschild, Messrs. N. Rothschild and Sons, Baron Schröder, Mr. H. J. Veitch, Mr. N. N. Sherwood, Mr. C. Czarnikow, Mr. A. W. Sutton, and Mr. G. Monro.

The committee are happy to announce that the following legacies have been received: £457 5s. 11d. from the late Mr. J. M. Thomson, formerly a gardener to his Majesty King George III., the interest to be devoted to the special benefit of a widow or widows; and £100 from the late Colonel Thomas Page, formerly a life member of the institution. They also thankfully acknowledge the receipt, just before the close of the year, of special donations to the general fund of £50 from the Royal Scottish Horticultural Society, and £26 5s. from the Royal Caledonian Horticultural Society. In common with other charities, the committee have to deplore the removal by death of several friends and supporters, amongst whom may be mentioned the late Dr. Hogg, a vice-president and trustee, who for many years took a warm and practical interest in the institution, and the late Mr. Richard Chrimes, who for upwards of thirty years had been a liberal subscriber to its funds, the late Lord Hindlip, and J. Travers Smith, Esq., both of whom had been annual subscribers for many years. They have also to record that, in consequence of advancing age, Mr. John Lee has felt compelled to relinquish his position as a trustee of the institution. From its foundation Mr. Lee has been one of its warmest friends, and whilst accepting his resignation with the deepest regret, they know that, as long as he may be spared, he will ever continue to take a special interest in its welfare. It is a source of much gratification for the committee to notify that the Hon. Walter Rothschild and Bruno Schroder, Esq., have consented to fill the vacant trusteeships, and they desire to express their sincere thanks to these gentlemen for so kindly giving their services in this way to the institution.

In concluding their report, the committee have to make the welcome announcement that the fifty-ninth anniversary dinner in aid of the funds will be celebrated on June 8 next at the Hotel Metropole, when his Grace the Duke of Portland has kindly undertaken to preside, and from a long experience they are encouraged to hope that all those friends who have the well-being of the charity at heart will again do, in this sixtieth year of its history, all in their power to ensure the success of the anniversary. And, whilst rejoicing in the solid prosperity of the charity, they still earnestly invite the kind co-operation of its present supporters in procuring new subscribers, especially amongst gardeners and those who may, at some time, be compelled to seek its assistance, so that its work may be not only fully maintained but enlarged, and the ever-increasing number of applicants helped and benefited.

We have audited the accounts and certify the same to be correct, and are pleased to state we have found the books well and accurately kept. We have also satisfied ourselves that the securities of the invested funds are in the hands of the bankers.

(Signed) THOMAS MANNING, THOMAS SWIFT, J. WILLARD, Auditors.

The adoption of the report was moved by the Chairman, who remarked that the last year was the most successful of the institution; he deplored the loss of two able trustees. He referred to the Thomson legacy, and stated that the interest from this would go as an annual pension to the widow, who just misses being elected as pensioner at the present election, provided the meeting considers the case suitable. After a few more remarks, with special reference to the success of the Victorian Era Fund, the motion was seconded by Mr. Gardener, and carried, together with a vote of thanks to the committee. Mr. Harry Veitch, on the proposition of Mr. A. Outram, was re-elected treasurer, and awarded a vote of thanks for past services. Mr. G. Wythes proposed Mr. G. J. Ingram be re-elected secretary; this motion, seconded by Mr. Osborne, was carried, and Mr. Ingram suitably responded. Mr. W. G. Morgan moved that Messrs. W. Denning, James Douglas, N. N. Sherwood, J. H. Veitch, and G. Wythes be re-elected members of the committee; and that Messrs. E. Ranger Johnson and Mr. Gleeson be re-elected members of the committee, in room of Messrs. R. Milligan Hogg and Thomas Glen, who retire. After being seconded by Mr. Manning, this was carried.

Mr. J. Hudson proposed the re-election of the auditors; after being seconded Messrs. Manning, Willard, and Swift were duly re-elected auditors. The arbitrators were also re-elected, and a vote of thanks accorded them. It was then proposed by Mr. W. Denning that Messrs. John Battersby, John Berry, Daniel Boreham, George Daniels, William Davidson, Thomas Ffoulkes, John Mitchinson, John Perkins, John Rolfe, and Silas Warr, whose cases have been investigated, and come within the terms of Rule III., 5, be placed on the pension list without election from January 1, 1898. No other business coming before the meeting, and all the formalities having been fulfilled, the chairman brought the meeting to a close, and proposed that Messrs. T. Manning, A. Outram, and E. J. Monro be elected scrutineers of the ballot. The meeting then broke up to await the result of the election.

RESULT OF BALLOT.

The poll was declared at 4.50, when the following were found to have been successful: Henry Ellis, Cheshire, 4,249 votes; Thomas Bundy, Bournemouth, 3,900; Robert Begbie, St. John's Wood, 3,878; James Baker, Devon, 3,868; William Wood, Finsbury Park, 3,790; David Cornell, Addlestone, 3,663; George Hewitt, Croydon, 3,651; Edwin Thomas, Shrewsbury, 3,550; and Lydia Rose, Derby, 3,534. In accordance with the terms of the Thomson Bequest, Elizabeth McCulloch, Charlbury, was also elected, having gained 3,031 votes.

There were 1,152 spoiled votes, including 1,035 unsigned and 117 unpaid lists. Total number of votes polled 97,951.

NORTHAMPTONSHIRE HORTICULTURAL SOCIETY.

The annual general meeting of this society was held on Wednesday last at the Stag's Head Hotel, under the presidency of Councillor H. Law. The treasurer (Mr. A. Cockerill) presented a statement of accounts showing that the payments, £810 15s. 8d., exceeded the income by £25 8s. 10d. The secretary (Mr. W. B. Troup), in replying to a vote of thanks for his services during the past year said, that in 1890 they had a profit of £200; in 1891 they cleared £39; in 1892, £113; in 1893, £79; since then they had had deficits of £54, £21, £43, and this year, £25; but considering the numerous counter attractions on the August Bank Holiday, they had had a smaller loss than was at first anticipated. A. Drucker, Esq., M.P., was thanked for filling the office of president during the past twelve months, Earl Spencer being chosen for that post for 1898. It was decided to hold the next show at Althorp Park, on Monday and Tuesday, August 1 and 2.

THE FRENCH HORTICULTURAL SOCIETY OF LONDON.

Mr. Herbert Cutbush presided on Saturday evening last over the ninth annual dinner of the above-named society, and a very successful and enjoyable evening it was. As was the case last year the gathering took place at the Imperial Restaurant, Strand, and a numerous company assembled to do honour to the occasion. English horticulture was well represented in the persons of Messrs. Harry Laing, Harman Payne, H. J. Jones, W. Cutbush, J. Weathers, and others. After dinner was over the customary toasts and speeches were indulged in, and Mr. George Schneider, the genial president of the society, in introducing the chairman to the company, reminded them that Mr. Cutbush's position in the gardening world and the interest he took in the society were ample recommendations for their selection of him as chairman on this occasion, and very heartily proposed his health.

Mr. Cutbush replied, saying that ever since the society was started in 1888 it had been most successful, a fact that was very largely due to the ability of its officers and the enthusiasm of its members. Numerous additions to the roll of membership had been made during the past year, and it was interesting to record that besides being represented in every European state, the society had members also in America, Algeria, the Congo, and elsewhere. Financially there was good reason for congratulation, the society being at present in a much better positi than this time last year. Many valuable additions had been made to the library, which was one of the leading features of the society. The Bulletin had been improved, and the new one for 1898 will be still more so. He was pleased to raise his glass and invite them to drink to the continued success and prosperity the society, coupling with the toast the name of their worthy president, Mr. Schneider, who, in reply, briefly reviewed the work of the past year, and thanked the members for the spirit of comradeship that always animated them. He also attributed a large measure of the success to English friends who kindly fou room for many of the young men who desired places in this country. In conclusi he gave the toast of "The Visitors," to which Mr. Harman Payne replied.

At this point a little surprise was in store for Mr. Schneider, as Mr. Gachel arose to make him a presentation of a case of cutlery and an address on behalf of the new members. Mr. Schneider appropriately replied to this unexpected demonstration of good feeling towards him.

Vocal and instrumental music was excellently rendered, and as a close to the proceedings the company very heartily sang the English and French national anthems. Messrs. Cutbush and Sons, of Highgate, received a cordial vote of thanks for the floral decorations.

MANCHESTER AND NORTH OF ENGLAND ORCHID SOCIETY.

January 13.

The above society held a meeting on the 13th inst. at the Coal Exchange, Market Place, Manchester, and even at this dull season of the year many interesting exhibits were brought together. Lycaste Skinneri alba, shown by Mr. Leeman, was notable, as such a fine specimen is difficult to find. Odontoglossum deltoglossum Stevensi was a fine form, much in the way of O. excelle Cypripedium bellatulum album was the finest yet seen, and Cypripedium insigne Sanderæ, of which two plants were shown and one cut flower, without doubt w the true type. The members present were: W. Thompson, Esq., in the chair, and Messrs. G. S. Ball, W. Gent, G. W. Law Schofield, A. Warburton, H. Greenwood, W. Bolton, P. Weathers, J. Cypher, W. Stephens, R. Johnson, and J. Leeman.

Mr. Stevens, gardener to W. Thompson, Esq., Walton Grange, Stone, Sta gained awards of merit for Odontoglossum deltoglossum Stevensi and Cypripedi Calypso. Mr. J. Robson, Bowdon, showed a well-grown plant of Cypripedi Boxalli, for which the committee recommended a cultural certificate; C. P tianum reversum gained an award of merit. Mr. Hey, gardener to G. S. Ball, Esq., Ashford, Wilmslow, showed Cypripedium bellatulum album, which gained F.C.C., and C. Swinburnei magnificum, which gained an A.M. Mr. Edge, gardener to J. Leeman, Esq., West Bank House, Heaton Mersey, brought Lyc Skinneri alba, Odontoglossum crispum (A.M.), and several other fine orchi Mr. A. Warburton, Vine House, Haslingden, showed Cypripedium insigne Sa deræ and C. Mons. G. Trauffant (C. Morganæ crossed with C. Stonei). Mr. S. Gratrix, Old Trafford, Manchester, showed several good things, and Cypripedi F. S. Roberts (C. niveum crossed with C. Curtisi) was a gem, gaining a F.C.C. Mr. Johnson, gardener to T. Statter, Esq., Stand Hall, Manchester, had sev good orchids; Mr. Rogers, gardener to O. O. Wrigley, Esq., showed Cypripedi Lathamianum roseum giganteum, C. Argus Moensi, Selenipedium leuchorrod and C. Wallærtianum pallidum; Mr. D. Lord sent C. Lathamianum giganteum.

The next meeting is to be held on February 10.

THE SCOTTISH HORTICULTURAL ASSOCIATION.

The annual meeting of this popular and useful society was held in the society rooms, St. Andrew's Square, on Tuesday, January 11. There was a crowd meeting, Mr. Todd, the retiring president, who was re-elected, in the chair. appeared from the secretary's report that the association was founded in 1 with some one hundred members, and that it has increased every year since, it now numbers some six hundred members; one hundred and fifty have added to the roll of members during the year just closed. The following bearers were chosen: Honorary President, the Duke of Buccleuch; Preside Mr. M. Todd; Vice-Presidents, Mr. P. Laird and Mr. James Grieve; Secret Mr. B. Laird; Assistant Secretary, Mr. B. Murray; Treasurer, Mr. Alex M'Kenzie. The society, as already announced, has given some £250 of its p to local and horticultural charities. The total income as appears from the treasurer's report from the great chrysanthemum show was £1,264 7s. 8d.; the expenditure £1,189 6s., leaving a balance of some £75, which with the ordinar income of the association reaches the sum of £164. Thus financially and culturally this association is in a most prosperous condition.

ISLE OF WIGHT CHRYSANTHEMUM SOCIETY.

This body held its annual meeting on Saturday, the 15th inst., when there a large muster of members. Dr. J. Groves, B.A., presided. The balance and report were unanimously adopted. The former showed that the so a balance in hand of about £18. The question of an Isle of Wight cham prize was fully discussed, and afterwards left to a sub-committee for deci Charles Seely, Bart., was re-elected president; Dr. Groves, chairman; Coombes, treasurer; and Mr. C. H. Cave, hon. secretary for the ensuing

Proposed Trials at Chiswick.—The trials to be conducted in R. Gardens during the current year comprise zonal pelargoniums for summer blooming and indoor blooming in summer, chrysanthemums for blooming in early autumn, violas, fuchsias for greenhouse decoration, pen for border plants, saxifrages for rockwork and borders, shrubby spir cannas, new early potatos, new peas, new tomatos, and radishes.

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forth coming exhibitions and meetings, and are requested to advise us concerning change of dates

Mushroom Cultivation.—F. W. N., Southampton: A handy little book on the subject is "Mushrooms for the Million," published at 171, Fleet Street, E.C., price 1s. 2d., post free. An article on "Mushrooms for Exhibition" will shortly appear in these columns.

Russian Salsafy.—G. S., Aberdeen: We are not aware that any form of salsafy is called Russian salsafy. Salsafy is the popular name of Tragopogon porrifolium, a plant common in Northern Europe, and naturalised in Britain. You may take it that no better forms of this vegetable are to be found than those offered by the leading seedsmen in Britain.

Melons.—McA., N.B.: Deeply ribbed melons are not now much grown, and as a rule those without ribs are better flavoured and more handsome. Two good scarlet-fleshed varieties are Syon Perfection and Blenheim Orange, and two good green-fleshed sorts, free and rich, are High Cross Hybrid and Hero of Lockinge; the latter has a very pale flesh, but is a handsome and luscious fruit. About four to six fruits to a plant will be sufficient for your purpose.

Potash for Cherry Trees.—S. G. R., Kent: The best and cheapest potash manure for your purpose will be muriate of potash. This should be used at the rate of one or two hundredweight per acre, and no delay should be made in its application, as autumn dressings are better than spring ones. Muriate of potash is very suitable for light and peaty soils. Kainit is a good artificial manure for orchards; it contains about 32 per cent. of potash, and should be applied at the rate of six to eight hundredweight per acre. Doubtless you are aware that wood ashes form a splendid potash manure.

Gas-heated Boilers.—"Perplexed" asks: "Will any reader who has had experience with greenhouse boilers heated by gas, kindly give his opinion of same, as I have one under my charge which is not quite satisfactory? It is one of Fenlon's patent gas boilers, fitted with two burners, set in brickwork covered with cement, and with outlet for fumes outside the house. The flow and return pipes pass through the woodwork under the stage. The pipes have been tested several times, and there appears to be no escape of gas that could find its way into the house. There is plenty of heat if both burners are used, or they can be regulated; the water has the same appearance as water in a boiler heated by a fire, and yet there is a peculiar faint odour in the house which causes flowers to wither and foliage to turn a sickly colour as though over-watered. I have other houses warmed by fire-heated boilers, and the difference in the plants in them is at once apparent, and to the advantage of the plants." Answers on this subject will oblige.

Maggots in Cineraria Foliage.—A. B. C.: Your cinerarias have been attacked by a pest similar to if not actually the same as the Celery Fly (*Tephritis onopordinis*). The fly deposits its eggs upon the foliage during summer and autumn, and as the grubs hatch they penetrate the cuticle and feed upon the substance of the leaf. This causes the blistered appearance so frequently seen celery foliage, and in a lesser degree in celery leaves; in the latter one can trace the progress of the maggot by the white lines caused by the channel it has eaten. The pest will be found at one end of such channel or gallery, and should be killed by pressure between the thumb and fore-finger. If the plants are held so that the leaves come between the eyes and the light it is also possible to detect the grubs. The fly is most dangerous in hot, dry weather, consequently it is a necessity that young cinerarias be placed in a cool, moist position. An occasional spraying with weak tobacco liquid will render the foliage distasteful to the fly and prevent the deposition of eggs. At present nothing can be done beyond killing the maggots, removing the badly infested leaves, and gently stimulating the plants by the use of a little liquid manure.

Moving Large Palm and Tree Fern.—S. F. C., Crouch Hill: There should be no difficulty whatever in shifting the palm to the centre of the house. Take out the tree fern as carefully as possible, so that neither it nor the roots of the seaforthia are damaged; the fern will stand rougher usage than the palm. Wrap the roots of the tree fern in a Russian mat, and then place the specimen in a warm greenhouse, where the mat and roots can be kept moist; also moss the trunk along the upper half of its length at least, and keep moist until eventually the stem is cut and placed in a tub or pot. Remove most of the fern fronds. Having disposed of the fern, make a deep and large hole in the bed where it stood, carting away the old soil. Then, allowing as large a ball of soil as possible, work round the roots of the palm, and as the work proceeds plank up the sides so that the roots will presently be boxed up; then work underneath the mass and push planks under, subsequently fastening all the wood together securely. It will be an easy matter to excavate sufficiently to allow the passage of the palm to where the tree fern formerly stood. If the bottom of the bed is not solid, lay down a couple or more of stout planks, and then by means of poles as levers and three rollers made of short lengths of slender scaffold poles, it will be easy to effect the transfer. The rollers should be as wide as the ball of the palm. Have some good soil ready and warmed in the house, and as soon as the palm is in position remove the planks and pack the soil around the roots. Finish off with a watering with tepid water. We have seen far larger palms than yours moved with success.

Manuring for Potatos.—Rex, Ely: The dressing of kainit which you propose is too large; you would be wasting money to give it to such land. A far better dressing, especially as you intend following the potatos with strawberries, would consist of five hundredweight of kainit and three hundredweight of superphosphates per acre; this would also help the fruit trees. You would have to lift the potatos for early sale, as they would not be in a ripe condition and fit for storing at the time you intend to plant the strawberries. Beauty of Hebron is a good variety for the purpose. A comprehensive work upon potatos is "The Potato in Field and Garden," by W. J. Malden, price 3s. 6d., and obtainable from W. A. May, 150, Strand, W.C. The weight of seed potatos required per acre varies with the size of the sets. Twelve to fifteen hundredweight per acre will be sufficient if good sets are used, that is, those that pass through a sieve of two-inch mesh but will not pass through one with inch and a half mesh. A ton of larger sets would be needed.

Spot on Apples.—J. D., Devon: The black spots upon the apples are caused by a fungus known as Apple Scab (*Fusicladium pyrinum* or *Cladorsporium dentriticum*). Anything that can be done to assist the tree should be done at once, such as thinning out crowded growth, washing and liming the trunk and branches as far as possible, and also giving a good dressing of manure. If the surface soil for some distance round the tree can be removed and replaced by a good dressing of road scrapings, wood ashes, burnt refuse, and old potting soil well mixed together, then the tree will make new surface roots that will assist it in the struggle against the scab. In fact, whenever strong strong measures have to be taken for the removal of a pest that is sapping the health of any plant and spoiling the crop, then feeding at the roots should also be done. A spraying with a weak solution of carbonate of copper should be given while the trees are dormant, and with a weak solution of Bordeaux mixture when the young leaves are expanding and before the flowers open; for the latter spraying the proportions of the ingredients should be 6 lb. of lime and 12 lb. of sulphate of copper to 100 gallons of water. No spraying should be done while the trees are in flower. As the foliage becomes stronger, and when the fruits are well formed a slightly stronger solution can be used, but if the mixture above given is applied in the form of very fine spray about it it may be repeated at intervals of about three weeks until fear of the disease is past. We have frequently given in these columns the method of mixing the ingredients of Bouillie Bordelaise.

Names of Plants.—C. H., Axminster: Jasminum nudiflorum.

A. B. C.: The specimens were not in a recognisable condition; not being packed in a damp moss or other material they were badly shrivelled, and also, owing to the flimsy nature of the cardboard box, they came to grief during transit. Light tin boxes are the best for sending specimens in. Neither name or address were sent.

B. J., Romford: 1, Euphorbia splendens; 2, Hoya carnosa; 3, Eulalia zebrina; 4, Epiphyllum truncatum; 5, Ophiopogon Jaburan variegatum; 6, Scirpus riparius, commonly known in garden as Isolepis gracilis; 7, Centaurea ragusina.

B. S. L., Hartlepool: 1, Acacia lophantha; 2, A. verticillata; 3, Asparagus Sprengeri; 4, Panicum plicatum.

R. D. B., Westgate: 1, Ixora Williamsi; 2, Asplenium biforme; 3, Maranta zebrina; 4, Cyanophyllum magnificum; 5, Gymnogramma gloriosa schizophylla; 6, G. peruviana.

Names of Fruit.—Rev. J. D., Devon: The large apple is Roundway Magnum Bonum, and the small one Five-crown Pippin.

O. C., Brentwood: 1, Bramley's Seedling; 2, Round Winter Nonsuch.

J. B., Ealing: 1, Catillac; 2, Easter Beurre.

F. R. M., Nantwich: 1, Lord Derby; 2, Mére de Mènage; 3, Winter Nelis.

W. S., Wolverhampton: 1, French Crab; 2, Ribston Pippin.

R. G., Ross: The cardboard box did not well withstand the somewhat rough usage of the Post Office authorities. So far as we can make out the fruits are: 1, Beurre d'Aremberg; 2, Beurre Delfosse; 3, Downton Pippin.

MARKETS.

Covent Garden.

AFTER a long spell of open weather and large supplies of vegetables, there is now a shortening in the supply of green stuffs. Good Brussels sprouts realise high prices, and there is a slight general upward tendency. Fruit in moderate supply, and chiefly from Canada, United States, and France.

FRUIT.—English apples, 4s. 6d. to 15s. per bushel; Nova Scotian and American, 12s. to 35s. per barrel; French pears, 4s. 6d. to 6s. 6d.; Californian, 8s. to 10s. 6d. per case; English grapes, 1s. 3d. to 2s. 6d. per lb.; Almeria, 10s. to 18s. per barrel; pineapples, 1s. 6d. to 5s. each; bananas, 5s. to 10s. per bunch; lemons, 6s. to 18s. per case; Canary tomatos, 10d. to 1s. 6d. per tray, 3s. to 4s. 6d. per case; French chestnuts, 6s. to 9s.; Italian, 12s. to 14s. per bag; Valencia oranges, 8s. to 16s. per case; Jaffa, 8s. to 12s. 6d.

FLOWERS.—Arums, 3s. to 5s.; carnations, 1s. to 3s.; chrysanthemums, 1s. to 3s.; gardenias, 3s. to 5s.; Lillium Harrisi, 4s. to 6s.; tea roses, 6d. to 1s.; pink roses, 1s. to 3s.; cattleyas, 6s. to 10s.; Odontoglossum crispum, 1s. 6d. to 4s.; tulips, 6d. to 1s.; and tuberoses, 6d. to 9d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; chrysanthemums, 6s. to 12s.; marguerites, 2s. to 4s.; mignonette, 2s. to 4s.; pelargoniums (scarlet), 6s. to 12s.; and violets, 1s. 6d. to 2s. per dozen bunches; azaleas, 9d. to 1s. 6d.; stephanotis, 4s. to 6s.; white narciss, 1s. to 2s.; Roman hyacinths, 6d. to 1s.; lily of the valley, 1s. to 2s.; and pelargoniums, 6d. to 1s. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 3s. to 4s. per bunch.

VEGETABLES.—Celery, 9s. to 15s. per dozen rolls; sprue, 5s. to 7s. per dozen bundles; turnips, 3s. to 3s. 6d.; carrots, 2s. 6d. to 3s.; parsley, 1s. 6d. to 2s. greens, 2s. to 2s. 6d. per dozen bunches; shallots, 2s. to 2s. 6d.; mushrooms, 6s. to 8s.; garlic, 3s. to 4s. per 12 lb.; French endive, 1s. 3d. to 1s. 6d.; lettuce, 10d. to 1s.; cucumbers, 4s. to 7s.; cauliflowers, 1s. to 2s. 6d. per dozen; Brussels sprouts, 1s. 3d. to 1s. 9d. per half sieve; beetroots, 2s. to 3s.; parsnips, 2s. 6d. to 3s. 6d.; cabbages and savoys, 3s. 6d. to 5s. 6d. per tally; asparagus, 4s. to 5s. per bundle.

Borough Potato Market.

A very quiet trade prevails, and there is a downward tendency in prices, although supplies are slightly smaller than usual.

Dunbars, 115s. to 125s.; Hebrons, 90s. to 105s.; Snowdrops, 85s. to 95s.; Bruce, Maincrops, and Sutton's Regents, 80s. to 90s.; Reading Giants and Saxons, 80s. per ton; Belgians, 3s. 9d. to 4s.; Germans, 4s. 3d. per bag.

OBITUARY.

MR. MAX DEEGEN, a well-known dahlia grower and nurseryman, died recently at Köstritz, Thuringia, at the age of fifty-six years. As a raiser of new dahlias Mr. Deegen will be widely missed.

MR. MICHAEL LAURENCE, an able old gardener, who had long had charge of the flower gardens at the residence of Mrs. W. Gilbert Tuck, Tostock House, Suffork, died a few days ago. He had held his position since 1847, and, though eighty-two years of age, was active and capable to the last.

The mean reading of the Barometer during the week at Greenwich was 30·25 inches, and that of the Thermometer 41°·8, the latter being 3°·8 above the week's average in the 50 years 1841—90. The direction of the wind was variable, the horizontal movement of the air being 55 per cent. below the week's average in the 16 years 1860—75. The duration of registered bright sunshine in the week was 3·5 hours. No rain was measured during the week.

ENGAGEMENTS FOR THE ENSUING WEEK.

AUCTIONS.

MONDAY, WEDNESDAY, AND THURSDAY, JANUARY 24, 26, AND 27.—Border Plants, Rose and Fruit Trees, Shrubs, &c., at J. C. Stevens's Rooms.

TUESDAY, WEDNESDAY, THURSDAY AND FRIDAY, JANUARY 25, 26, 27, AND 21.—Lilies, Palms, Azaleas, Tuberoses, Orchids, &c., at Protheroe and Morris's Rooms.

Hampton, Middlesex.

MALMAISON CARNATION.
Thousands of plants in the finest health and vigour possible, in 4-inch pots, 6s. per dozen.
W. HARDY and SONS, Holmes Chapel, Cheshire.

GREEN PEAS—JUNE TO NOVEMBER.

A correspondence was raised in the Daily Press last Autumn upon the shortness of the season when Green Peas are available, both in gardens and on the market. We now offer the following as representing the best collection selected from 1,024 rows we had under trial last season. It would be difficult for us to give precise dates for putting the seed into the ground, as so much depends upon soil and situation. Successional Sowings may be made any time between these dates, and the last sowing not later than the second week in June.

NAME.	DESCRIPTION.	HEIGHT. ft.	WHEN TO SOW.	EXPECT READY TO PICK.	CARRIAGE FREE. Per Pint.	CARRIAGE FREE. Per Qrt.

SEED LIST

(Free on Application).

FEATURES.

Alphabetically arranged.
Best sorts, in heavy type, can be seen at a glance.
Probably the most explicit practical instructions for cultivation ever published.
Many hints and recipes for cooking and serving the various vegetables.
Directions for the storing and forcing of vegetables.
Medicinal qualities of many vegetables and herbs.
Prizes of £5, £3, two of £2, and £1 offered for Photographs of Horticultural Subjects (see page 2 of Catalogue).

THE LIST, containing 93 pages, and a profusion of illustrations, shows (A) **What to Grow**; (B) **How to Grow it**; and (C) **What to Do with it when Grown**; and has been described by an agent on one of the largest estates in England as a BOOK OF REFERENCE.

Another Customer, testifying as to quality, writes: "I should like to add that all the Seeds, &c., purchased from your establishment during the past 14 years have been of the very best quality, and have given great satisfaction."

COMPETITION DEFIED!
OUR UP-TO-DATE SEED CATALOGUE

for 1898 proves that our prices are far below any others. We guarantee our Seeds to be

NEW, GENUINE, and RELIABLE.

In dealing with us great benefit is derived, as we do not spend our clients' money in costly advertisements; nor is our Catalogue a work of art, entailing enormous expense (needless to ask who pays for this). We have shown what we can do in the BULB TRADE on the score of economy and excellence, and we shall supply our Seeds on the same basis. Therefore, send for our Catalogue (free), and judge for yourselves.

NATIVE GUANO.

BEST AND CHEAPEST MANURE FOR GARDEN USE.

Price **£3 10s.** per ton in bags. Lots under 10 cwt., **4s.** per cwt., 1 cwt. sample bag sent carriage paid to any station in England on receipt of P.O. for **5s.**

Extracts from 22nd annual collection of reports:—

NATIVE GUANO FOR POTATOS, VEGETABLES, &c.

C. H. TINDALL, Bardney: "Used for Potatos. Result very satisfactory; yield much above average. A splendid manure." G. WATTS and SONS, Bournemouth, report: "Good for general purposes. Grand for all Root Crops, Tomatos, and Cucumbers. Find it so cheap; and it does not exhaust the ground like other manures."

NATIVE GUANO FOR FRUIT, ROSES, TOMATOS, &c.

E. F. USHER, Sidcup: "Potatos and carrots, splendid crops; Peaches, Nectarines, &c., splendid. Should not like to be without it on any consideration." G. STONARD, Gardener to Sir A. T. Watson, Bart.: "Used for seven years for Peaches, Grapes, Tomatos, Cucumbers, Roses, and Chrysanthemums with excellent results."

Orders to the **Native Guano Co. (Limited)**, 29, New Bridge Street, Blackfriars, London, where pamphlets of testimonials, &c., may be obtained. Agents Wanted.

EPPS'S COCOA.

EXTRACT FROM A LECTURE ON "FOODS AND THEIR VALUES," BY DR. ANDREW WILSON, F.R.S.E., &c.—"If any motives—first, of due regard for health, and second, of getting full food-value for money expended—can be said to weigh with us in choosing our foods, then I say that cocoa (Epps's being the most nutritious) should be made to replace tea and coffee without hesitation. Cocoa is a food; tea and coffee are not foods. This is the whole science of the matter in a nut-shell, and he who runs may read the obvious moral of the story."

GARDENER (Head Working); married; good experience in five counties; leaving through death; good character and references.—GARDENER, 9, East Street, South Molton, Devon.

GARDENER (Head Working, or good single-handed); practical man Inside and Out; three years seven months' excellent character from present employer; age 34; married when suited.—G. CROWTER, Pickhurst Manor, Beckenham, Kent.

GARDENER (Head Working); age 32; married; experienced in chrysanthemums, orchids; stove and greenhouse; plants and kitchen garden; 3½ years' good character from last employer.—R. PLACE, 1, Clarke's Cottages, George Lane, Wanstead, Essex.

GARDENER where another is kept, or Good Single-handed where help is given; single; 13 years' practical experience Inside and Out.—A. M., Post Office, Little Baddow, Essex.

GARDENER (Second, in Private Establishment); Inside preferred.—REUBEN DARK, Moreton Gardens, Bideford, would have pleasure in recommending Frederick Pugsley; age 21; three years and eight months' good character.

GARDENER (Under).—Young Man wants situation in the Houses; good character and knowledge of work; bothy preferred.—H. PENN, Lyminster, Arundel, Sussex.

GARDENER (Under, Inside or Out), age 20; one year in present place, 3½ previous; fair knowledge of inside and out; good character from present and previous employers; gentleman going abroad. — HORACE COLLINS, Canada Lodge, Rogate, near Petersfield.

GARDENER (Under or Single handed).—Wanted by Young Man; age 21; well up in greenhouse, fruit, flowers and kitchen garden; three years' good reference at present situation.—GEORGE GAMMON, Watchbell Street, Rye.

GROWER.—Age 28, London and provincial experience in soft-wooded stuffs, Fruit, Bulb and Lily forcing.—E. P[illegible], Vineries, Scotby, Carlisle.

GROOM-GARDENER, age 28; well up in driving, and all branches of the garden; 6½ years' good character.—H. H., care of Mrs. England, 8, Acre Road, Kingston, Surrey.

IMPROVER.—Gardener's Son (aged 20), seeks situation as above; over two years' experience Inside; gentleman's garden preferred; quick, and willing to learn.—H. BENSLEY, Victoria Nurseries, West Humberstone, Leicester.

JOURNEYMAN (First).—Mr. Lambert, Burton Constable, Hull, will be pleased to recommend a Young Man as above; age 23; highest testimonials.

JOURNEYMAN (First), in Good Establishment, or Gardener (Second); age 24; first-class testimonials; abstainer; disengaged.—E. ROGERS, 158, Sunny Hill Road, Streatham, S.W

MANAGER or Foreman.—Over 20 years' experience in growing plants, cut flowers, tomatos, &c., for market and retail; good references.—ROBERTS, Cæsarean Nurseries, Five Oaks, Jersey.

RICHARD SMITH and CO., beg to announce that they are constantly receiving application from Gardeners seeking Situations, and that they will be able to supply any Lady or Gentleman with particulars, &c.—St. John's Nurseries, Worcester.

SHOPMAN, ASSISTANT, requires situation; age 22; eight and a half years' experience in all branches, including two years in a London Wholesale House.—A. F., 63, Roxburgh Street, Kelso.

WANTED Situation as GARDENER, Second, in good establishment; ten years' experience; age 26; past four years at Maristow; last two as Foreman; highly recommended from Maristow and previous places; bothy preferred.—HARRIS, Whitstone Head, near Holsworthy, North Devon.

Situations Vacant.

Advertisements under this heading are charged 2s. 6d. for Four lines (32 words), and 6d. per line of eight words after.

GARDENER WANTED.—An industrious, steady Man; age 30 to 35; married; must understand kitchen and flower garden, vinery and conservatory; wages, 22s. per week and cottage; first-class references required.—Apply by letter, with all particulars, to Mr. BLAYLOCK, Blaxton, Uppingham.

HEAD GARDENER.—Wanted a Man from 35 to 40 (married, without family, and an abstainer preferred), who thoroughly understands the management of vines, orchids, stove and greenhouse plants, lawns, and kitchen garden.—Apply, by letter only, stating qualifications and length of last service, to G. T., Green Hill Park, New Barnet, N.

WANTED, an Energetic YOUTH for the Houses; one who has had some experience and who wishes to learn; must be able to take turn duty; wages, 12s. per week, with bothy and vegetables.—W. A. COOK, Compton Bassett, Colne, Wilts.

WANTED.—Young MAN in Soft-wooded Department; must be well up in watering, potting, tying, &c. Permanent situation to a suitable man; wages to commence, £1 per week.—Apply H. J. JONES, Ryecroft Nursery, Hither Green.

WANTED, GROWER of POT VINES. Send reference.—WILL TAYLER, Hampton, Middlesex.

NOTICE. AN EMPLOYMENT REGISTRY DEPARTMENT IS CONDUCTED IN CONNEXION WITH THE "GARDENERS' MAGAZINE," AND THE CHARGE FOR AN ADVERTISEMENT INCLUDES A FREE ENTRY ON THE REGISTER FOR ONE MONTH. IF NOT SUITED AT THE END OF THAT TIME, AND IT IS DESIRED THAT A NAME SHOULD REMAIN, IT WILL BE CONTINUED FOR A FURTHER PERIOD UPON RECEIPT OF A REQUEST. IMMEDIATE NOTICE MUST BE GIVEN WHEN AN ENGAGEMENT IS SECURED.

A List of Gardeners on the Register will be supplied upon application to the Publishers if a stamped envelope is forwarded, addressed 148 and 149, Aldersgate Street, London, E.C.

BARR'S SEEDS

FINEST SELECTED STRAINS OF TESTED GROWTH

Barr's Ne Plus Ultra **French Bean.**
A fine forcing variety, very early, and producing an abundance of fine pods. Per quart, 1s. 6d.

Barr's Earliest French Shorthorn **Carrot.**
A favourite for soups, and extremely early; the best variety to sow in frames. Per oz., 10d.

Barr's Pride of the Market **Cucumber.**
A specially fine selection, dark green, and of handsome shape, a favourite in Covent Garden Market. Per packet, 1s. 6d.

Barr's Improved Telegraph **Cucumber.**
A fine selection, handsome straight fruit, of fine flavour, very prolific. Per packet, 1s. and 1s. 6d.

Barr's "Eureka" **Melon.**
A grand new scarlet-fleshed variety, fruit large and densely netted, flavour delicious, heavy cropper and early; a splendid exhibition variety. Per packet, 1s. 6d. and 2s. 6d.

Barr's First of All **Radish.**
Fine little, short-leaved, very early Radishes, s *white.* Each, per oz., 6d

Barr's Early Ruby **Tomato.**
Large, solid, bright scarlet fruit, of fine form; an abund cropper, and best *first early* Tomato. Per packet, 1s.

Barr's Thick-fleshed **Tomato.**
Surpasses all other varieties for depth of fruit, solidity of flesh, high quality, and heavy cropping. Per packet, 1s.

Barr's Seed Guide *sent free on application.*

NOTES OF THE WEEK.

ORCHID COMMITTEE AWARDS.

We are pleased to receive proofs that our remarks on this important subject, in our issue of the 22nd inst., have evoked much interest and are being widely discussed by members of the several committees of R.H.S., because the result of the discussion will, we have no doubt, be some reduction in the number of the awards. We have received a large number of private letters relating to the question, and while the majority of the writers are in full agreement with us, some of our friends appear to be rather hurt because we directed attention to the paragraph in the Council's report, in which the committees are urged to be less generous in their awards, Those who take that view of the case have not, we fear, read what we have written with the proper degree of care, for had they done so they would have seen that our object was to induce the members of the committees to recognise the importance of the advice of the Council and by acting upon it, enhance the value of the distinctions conferred upon really meritorious novelties. We would suggest that they again read the "note" in the first column of page 35, and if they do that we shall be greatly surprised if they do not write and say that we have dealt with the matter with some degree of mildness. Mr. de Barri Crawshay, of Rosefield, Sevenoaks, writes, under date of the 22nd inst., with reference to our remarks on the Orchid Committee as follows:—"Anent your article in to-day's issue *re* The Awards to Novelties, you are specially pointed in your remarks upon the action of the Orchid Committee. Let me at once state, my subjoined remarks are absolutely a personal reply, and not coming from the committee. A great deal is said against the Orchid Committee in many ways, and perhaps at times there are points that could be improved upon, but I think if you were upon it you would be in a different train of ideas towards it. I have looked over the 1897 F.C.C.'s and cannot see an instance of one being given to a 'plant in general cultivation.' Varieties are the great marks in orchids more than in other families, and the type may be grown all over the country, but a fine variety turns up and be well worth an F.C.C. Considering the large number of 'subjects' to adjudicate upon, it is surprising that more false steps are not made, when you consider that all members have their especial favourites; and after all, human nature leans to that which it likes best, and invariably thinks it better than something less esteemed If you had analysed the F.C.C.'s and A.M.'s given by all the committees, you would see the Orchid Committee gave but 25 out of 54; and 91 out of 346, respectively. Taking the total of the plants that are submitted, I do not think you will find it a very excessive proportion, when you consider the hundreds of thousands that are imported and bloomed for the first time annually. If a 'marked advance' was required each time the end would soon come. Orchids are not, like carnations or anemones, raised from seed and bloomed and forgotten in a couple of years unless they are very good. I hope you will publish this letter, though I hardly expect you will voluntarily do so to evoke an argument the reverse of your article."

AWARDS TO OLD INTRODUCTIONS.

Mr. de Barri Crawshay is altogether wrong in supposing that we should hesitate to publish his letter because his views upon the question at issue are not in accordance with those we have expressed. We gladly welcome discussion, and there can be no proper discussion unless those holding divergent views take part in it. We are well aware that the work of the Orchid Committee has been criticised in some quarters, but much of the criticism has been quite undeserved, and we are fully persuaded that the members perform their duties with quite as much ability and care as do those belonging to other committees. Their specially weak point is, in our opinion, conferring distinctions upon plants in general cultivation, and we alluded to the practice because we believe these awards discount the value of distinctions conferred upon novelties of a meritorious character. If the consideration of the question is limited to the past year, it is not exact to use the term first-class certificates, for there was but one awarded in 1897; but when writing we had in mind the practice that has obtained for several years past. Mr. de B. Crawshay tells us he has not been able to find an instance in which a first-class certificate was in 1897 conferred upon a plant in general cultivation. But surely Cymbidium eburneum, which received that highly appreciated distinction at the meeting held March 9, may be so described. Again, Acineta Barkeri, which had a botanical certificate conferred upon it on September 7, and Dendrobium albo sanguineum and Oncidium papilio, which received awards of merit on April 13 and September 21, respectively, may be described as generally cultivated. If the three last-named species are not now met with in so many collections relatively, as was the case some years ago, it is simply due to their having been pushed on one side by the more beautiful hybrids and varieties of other species, for they are cheap enough to be within the reach of all who can afford to indulge in the luxury of an orchid house. We fully agree with Mr. de B. Crawshay, that new, distinct, and beautiful orchids, whether species, hybrids, or varieties, should receive the highest distinction; but we repeat that awards made by either committee to subjects which are neither new nor rare are undesirable, and should be unhesitatingly vetoed by the Council.

IMPORTED INSECT PESTS.

A study of Miss Ormerod's invaluable annual report on injurious insects demonstrates that the importation of foreign fruits has its risks as well as advantages, since thereby we are apt to receive not only additions to our desserts, but additions to the already too plentiful host of fruit-destroying vermin. Fortunately, however, experience has shown that in most cases the niceties of environments are such that the importations die out, some natural impediment to their increase cropping up during their life cycle which breaks its continuity and delegates them to the "unfits." Clearly an insect developed and modified by one set of climatal and other conditions, such as a different class of vegetation, so that its eggs are adapted to hatch simultaneously with the opening of the buds destined to nourish its offspring, would be fatally handicapped by material variation, either in the starting of new growth or the nature of such growth when developed. The eggs, too, framed to stand a severe and protracted winter, followed by a warmer spring than ours, would probably be addled by our variable winters, with their spells of mildness, and especially by our inconstant springs. Antipodean insects, too, must be additionally handicapped by the reversal of the seasons altogether, and it is difficult to imagine that imported individuals could defer the laying of eggs for six months so as to ensure their hatching at a favourable period, while imported eggs would be little more likely to remain quiescent for a much longer period than the normal one, and if they did succeed in hatching the inherited tendencies of the brood would probably lead to a misfit in the following season. In many cases the adjustment of an insect to the plant it feeds upon is extremely fine; not only is it in itself provided with precisely the jaw suckers and other apparatus best fitted to deal with the tissues and juices of the plants, but its reproductive cycle fits it also to a nicety, and it is doubtless due to this that certain varieties of plants, that is mere varieties of species, are proof against the vermin which prey upon the other members of their tribe, some subtle difference of texture, flavour, odour, time of maturation, or other reason, baffling the insect, until that in turn varies to fit and the immunity is at an end. Doubtless, too, the imported vermin is handicapped by lack of instinctive knowledge of the new foes, bird and other, which its new environment involves; but in any case it is clear that in this direction, as in all others, knowledge is power, especially such carefully correlated knowledge as Miss Ormerod steadily accumulates year after year for the benefit of every agriculturist or horticulturist who studies the lessons of caution and prevention which are inculcated by the data she provides. A full acquaintance with the life history of any organism is bound to reveal its weak points, and so give man a chance of dealing with it, while to attempt to do so in ignorance means, as a rule, but costly experiments and general failure.

VARIETY IN DESSERT FRUIT.

The question of so arranging the several departments of the garden devoted to fruit production as to ensure abundant and varied supplies extending over the longest possible period is one of the most important that could well engage the attention of practical horticulturists occupying responsible positions. There may be no great difficulty in obtaining plentiful supplies of certain kinds where the available space, both in the open and under glass, is equal to requirements, or in selecting varieties that are diversified in character; but it is not sufficient to consider these two points as distinct from each other, as is frequently done. They must be regarded as inseparable, and with them ought also to be associated the question of quality, for this should unquestionably be high in the case of dessert fruit to be consumed at home. We are disposed to assign a rather high position to variety in making arrangements for the maintenance of a supply of dessert fruit, for, to state the case generally, the employer and his family fail to fully appreciate the dessert when the same varieties of apples, grapes, pears, or other fruits are sent to table every day during the period they are in season. In some instances it may be necessary to do this, as when employers are desirous of having some particular varieties throughout their season. If an employer desires the Pineapple nectarine, the Royal George peach, or the Black Hamburgh grape as long as it may be available, it is the gardener's duty to provide it; but we are not now concerned with these exceptional cases in which the cultivator is not allowed any appreciable latitude in making a selection. We have in no way changed our opinions with regard to the planting of large collections, which have done so much to hinder the development of fruit culture in this country; but we have no wish to see fruit culture for home supplies carried out on precisely the same lines as those which must be followed in the production of fruit for market. In the latter case the planting of a limited number of varieties of proved excellence for market is absolutely necessary to success; but in table fruit a diversity in appearance and flavour is not less essential. Happily, this difference may be obtained without planting a single variety that is shy in cropping, or that produces fruit indifferent in appearance or quality, and in the case of all our dessert fruits a comparatively small number of varieties will suffice to give sufficient variety to add materially to the interest and enjoyment of the dessert, and to this extent only should selections be increased. More especially should proper advantage be taken of the wide range for selection afforded by the peaches, nectarines, plums, and cherries, and to plant due proportions of both early and late varieties. The mid-season varieties of these fruits will give a supply extending over a considerable period, provided several trees are planted, and these mostly on different aspects, but it may be stated as a general rule that it is more advantageous to maintain the supply by varieties ripening at different periods, provided they are equally good in quality. Were the value of variety in dessert fruit properly recognised we should more frequently see upon the table many of the excellent grapes which, if not equal in utility to the Black Hamburg and Muscat of Alexandria, are so finely flavoured as to justify their being grown where several structures are devoted to grape culture. The proper appreciation of the attribute in question would also have the effect of enlarging the selection of strawberries; not in the direction of planting inferior varieties, but of increasing the culture of those remarkable for the high quality of their fruit; and in the case of these fruits some extension in the range of selection is desirable, for of late there has been a tendency to unduly restrict the number of varieties, and to attach greater importance to size than to quality. Large collections cannot be too strongly condemned in private gardens, but unduly restricted selections place the private garden on the same plane as the market establishment, and greatly detract from the interest and enjoyment to be derived from it.

Violet Perfume.—For a long period much of the perfume sold as the product of the violet has been derived from a quite different plant, namely, the Florentine iris, and now we have to record as one of the most recent achievements of scientific chemistry, the production of an artificial perfume practically identical with that of violets. This substance, known as ionone, or artificial essence of violets, belongs to the class of ketones, and is a valuable product commercially. The production of artificial musk has also been satisfactorily accomplished, and, as indicating the value of the discovery, it may be mentioned that it is worth about £500 per pound.

The Witch Hazels are now flowering freely, and in several parts of the Royal Gardens, Kew, their bright flowers show up conspicuously amid the general dulness of vegetation at this season. Near the entrance to the Cool Orchid House is a round bed of considerable size occupied by half-a-dozen good specimens of Hamamelis arborea, a Japanese species with bright yellow flowers and deep purplish calyces; this is very effective now that the young trees are ten feet high and freely branched. The bed is suitably carpeted with Gaultheria procumbens. Not far from this bed are some circular masses of Crocus Sieberi and C. Imperati, now finely in flower. Daphne Mezereum, both white and purple flowered forms, brighten up the gardens, and also emit a delightful fragrance.

The Southampton Horticultural Society.—This well-known southern society has doubtless wisely resolved to abandon its customary August Bank Holiday flower show and fête for various reasons, but specially that the town seems now unable to furnish for so large a show a suitable site. But the exhibition has been held for so many years in succession that, like all similar shows, it had become somewhat stereotyped, and when that is so then public interest is lessened. It seems, therefore, to be a peculiarly happy thought on the part of the executive to arrange a great midsummer rose show, to be held of all places, too, in the huge pavilion on the Royal Pier, that juts out so charmingly into the Southampton Water. If the N.R.S. and the Isle of Wight rosarians give very practical support, this show should be, for the coming season at least, the leading rose tournament in the South of England. The local Harbour Board seem to have offered excellent facilities for a two days' show. The maritime surroundings are delightful indeed.

Buds and Stipules.—The uses of these important organs were discussed by Sir John Lubbock in a discourse delivered at a meeting of the Royal Institution a few days since. At the commencement of his lecture he showed a number of diagrams to illustrate the various ways in which the buds of plants were protected from the cold, and then proceeded to describe how in some cases protection was afforded by the old leaves and in others by the leaf-stalk, and how sometimes the bud had to protect itself as it were by means of a covering of hairs or of scales. The latter represented different parts of the plant sometimes corresponding to leaves, sometimes to stalks, sometimes to stipules, &c. Hairs in alpine regions served to keep off excess of moisture, or in dry and desert countries to prevent too free transpiration of moisture; or they might protect the leaves from insects and keep them warm. The most frequent use of stipules was to protect the bud, though they sometimes fulfilled the function of leaves. They varied considera in form, some being very wide, others very narrow. When the leaflets were la and broad they were broad, thus being able to protect the whole bud, whereas narrow elongated leaf only required a narrow stipule. Discussing why the seed leaves of plants always differed from the other leaves, Sir J. Lubbock found the explanation in the fact that these leaves, being folded in the seed, ha to conform to its shape. Similarly the bud influenced the form of the mature leaf. For instance, the curious shape of the tulip-tree's leaf was due, he believed, to the configuration of the bud, which contained the stipules, the stalk, and the leaf folded upon itself, the latter just occupying the space left by the tw former. Referring to the question why one member of a species of plants should possess stipules while another did not, Sir John Lubbock thought the evide conclusive that where stipules were present the leaf stalks were narrow, wh they were broad where there were no stipules. In conclusion, the lecturer referr briefly to the processes attendant on the fall of the leaf in autumn.

Export of Plants to Italy.—A correspondent writes from one of the principal Italian cities: "I wish that attention could be called to an importa matter, namely, the prohibition of every bulb or green leaf from England. Gr Britain, having neither vines nor phylloxera, did not join the Berne Conven Consequently, while plants and bulbs from every other European country, n matter how infected by phylloxera, are allowed entry here (with a certificate o origin), everything of the kind coming from England is rigorously excluded. T is to say, the Italian Government prohibits plants and bulbs from the one c free from phylloxera—not that they are therefore kept out, as there is an orga system of agencies who pass them in—for a consideration. The Ministry Agriculture in Rome is able to give a 'permesso' for this, but practically th a dead letter, being always refused."

Canadian Apples have lately fallen in price, even to the extent of 4s. to per barrel, as a consequence of the general complaint made by purchasers of th uneven, not to say dishonest packing. Quantities of barrels have been foun contain a considerable number of inferior samples in the middle while the top an bottom layers were of good quality. Unfortunately the distrust has become s great that those who have packed their fruit honestly are suffering as wel those who have been so deceitful.

Wireworms.—Though these insects are so destructive, it is only that measures are adopted to combat them by cultivators, and full advantage seldom taken of the few weak points presented by the habits of the pe Severe wireworm attacks frequently occur on broken up grass land, and if i these cases some efficacious treatment, such as the digging in of gas-lime, we uniformly adopted before attempting to raise a new crop, a large proporti of our annual loss from this cause would be forestalled. In March a commu cation was received by the Royal Agricultural Society from Mr. G. Per Smith, of St. Albans, suggesting the use of "mustard dross," a waste prod in the manufacture of mustard, as a substance likely to be of use against wir worm, and the Zoologist was instructed to make a series of flower-pot exper ment to test its efficacy. Mr. Colman, of Norwich, furnished some of th "dross," which is in the form of a fine powder or dust. It must not be confound with mustard cake; for it is much more pungent, containing, as ascertained by Voelcker, eighteen and a half per cent. of oil. After a thorough trial on small scale, the following conclusions were arrived at: (1) The dross is noxious to the wireworm, and fatal to them if they remain in it; (2) sown w the seed it keeps off the worm in the earliest and most vulnerable stage of th plant's growth; (3) if used too plentifully it delays the germination of the but there would be no likelihood of this with the quantities which the cultiva would probably use; (4) experiments on the small scale do not indicate th would be of any use as a top-dressing when the crop is up, as it has a effect on the plants themselves; (5) it seems eminently likely to be useful, if with the seed, in cases where wireworm is to be anticipated, as after gr clover in land much subject to wireworm; (6) it is very light, and wou to be mixed with ashes; (7) quantities equivalent to two and a half h weight per acre have given distinctly beneficial results in the pot experimen is unnecessary to say that flower-pot experiments are not always safe guides what will happen on the large scale, but the results were sufficiently ma make further experiments desirable.

Japanese Plums in South Africa.—With regard to the trials of J plums made in South Africa, Mr. E. Tidmarsh, Grahamstown Botanic G has reported to Professor Bailey, of Cornell, that the varieties, although n equal in flavour to the best sorts grown in Europe, have valuable proper this climate. For one thing, these varieties, so far as tried, grow freely gr the peach. A number of the European sorts refuse to grow on the peach, this is a drawback in two ways. First, the peach stock is, on the whole, adapted to this climate, and secondly, it is a difficult matter to raise plum stocks in this country.

Brigade-Surgeon Lieut.-Colonel Dr. George King, who was recently promoted to be Knight Commander of the most eminent Order of the Indian Empire, is director of the Royal Botanic Gardens, Seebpore, Calcutta, and superintendent of the Cinchona Plantations, at Darjeeling. Sir George King is a renowned botanist, and has rendered great public service in connection with cinchona cultivation in India. In the course of the year Sir George completes his term of service at Calcutta, and will be succeeded by Dr. David Prain, who for many years has been curator of the Herbarium at Seebpore.

Japanese Plums in America.—Professor L. H. Bailey, of the Cornell University, has recently issued another report upon Japanese plums that are now being extensively tried at Cornell and elsewhere. He says: "I am still convinced that the Japanese plums have come to stay. By this I do not mean that they are destined to supplant the domestica and native plums, but that they are bound to supplement those types with varieties that are adapted to particular purposes and conditions. As a class they are vigorous, hardy, and productive in tree, and the fruit is handsome, long keeping, and covers a long season. Thus far the Japanese plums have been comparatively free from black-knot, and until this year our trees have not been seriously attacked by the shot-hole fungus or leaf-blight. During the past season, however, this leaf-blight has been much worse upon the Japanese varieties than upon the domesticas alongside them, and this, too, in spite of the fact that they were thoroughly sprayed. The leaves did not drop to any extent, however, even though they were badly riddled by the fungus. It is our habit to set the wood of new varieties (either as buds or grafts) in the tops of Lombard plums, and several of the varieties have been fruited only in this way." Professor Bailey concludes by saying, "I never recommend varieties of any fruit for anyone to plant. For myself, I should still adhere to my list of four varieties of two years ago—Red June, Abundance, Burbank, Chabot. I should place as second choice Douglas, Berckmans, Satsuma, Hale, and Wickson, and should expect that the last two would rise, upon further acquaintance, to a place in the first rank. If I wanted a yellow plum I should take Georgeson, with Orgon for early. If I wanted the earliest varieties, without respect to size or quality, I should choose Berger, Engre, Earliest of All, and Willard."

Early Flowers.—Although the general press does not now deign to notice the traditional big gooseberry, yet when opportunity offers, such as the present very mild winter presents, for instance, there is a tendency on its part to labour the early hardy flower pars, which readers here and there furnish so abundantly. To gardeners generally, and to most ordinary observers, there is nothing new or special in these evidences of floral precocity. When the winter time is so mild, as is the present season, what wonder if flowers among other things be very much out of time or tune. But we have some flowers that always bloom in their proper season, let the weather be what it may, and of all these none is more constant, few more beautiful in its season, than is the Naked Jasmine. *(Jasminum nudiflorum).* This midwinter-blooming shrub has, indeed, had a fine time of it of late. It has been flowering profusely for some two months, quite unharmed; whether grown against a wall; whether the pretty yellow flowers be seen twinkling from out of ivy or grown as an ordinary shrub, it has been a lovely thing.

The Floral Decorations at Cheltenham, on the occasion of the New Club Ball, held at the Assembly Rooms, were of an exquisitely beautiful character, and added to the already long list of successes Mr. J. Cypher has obtained. In the ball-room the various recesses of the large end windows were tastefully filled with palms, crotons, dracænas, camellias, ficus, ferns, acacias, tulips, cinerarias, cyclamen, primulas, &c. In the sitting-out rooms Mr. Cypher excelled himself in the beautiful arrangements of plants, flowers, and foliage placed about the fire-mantels. The supper-room was, however, the most gorgeous so far as floral decorations are concerned, and here the floral arches on the central diamond table formed the leading feature. Those who have seen some of Mr. Cypher's best efforts in the artistic grouping of plants and flowers at our leading provincial flower shows, can readily imagine the grace and beauty produced at Cheltenham on this occasion by a clever association of ferns, palms, crotons, tulips, orchids of various kinds and hues—especially odontoglossums, cattleyas, and cypripediums—lilies of the valley, &c. The orchids were chiefly arranged in artistic vases, one species or variety by itself.

The Botanic Gardens at Buitenzorg, Java, is probably the most complete and remarkable tropical botanical institution of its kind to be found. Our readers will remember the illustrated account of this splendid Dutch establishment given in the Gardeners' Magazine of August 22, 1896. We refer to these matters now, because Dr. Treub, the gifted director, has issued a Hand Guide to the gardens, in English, accompanied by a plan.

A Public Park for Ventnor.—The "Garden Isle" has recently received a magnificent gift of several hundred acres of land, situated on the Downs overlooking the town. Mrs. Evans, the donor, is carrying out the wishes of her late husband in making this presentation, and the only restrictions are that the park is to be free to all, that no residential buildings be erected on it, and that public houses are prohibited. The inhabitants of Ventnor have publicly thanked Mrs. Evans for her munificent gift.

Total Eclipse of the Sun.—The observation of the total eclipse of the sun on the 22nd has been highly successful in India. At Magapur, the weather, according to the Sir J. Norman Lockyer, was excellent, and the various instruments were satisfactorily employed. At Talni the sky was perfectly cloudless, as for several days previously, and a considerable number of remarkably good photographs were taken. Some forty excellent photographs were taken at Jewar. The observations were also satisfactory at Buxar and other stations. The totality extended over one and a half minutes, but the darkness did not reach that of the eclipses of 1866 or 1896.

Plant Variation.—At the meeting of the Royal Botanic Society on the 22nd inst. the Rev. G. Henslow gave a lecture on "Plant Variation," which was fully illustrated by means of a large number of photographs reflected upon a screen. He described the various monstrosities, or departures from the normal structure, of different plants, and traced in many cases the gradual transition from the original to the "sport," showing how the character of the latter had become fixed or hereditary, and was now looked upon as quite the normal form. Amongst the donations received since the previous meeting was a specimen of Euonymus japonicus presented by Mrs. Doxat, of Hole Head, Dawlish. Attention was called to the fact that the specimen had borne fruit, a very rare occurrence in this country.

Horticultural Exhibition in Cairo.—The annual horticultural exhibition at Cairo was opened on the 14th inst. In several of the sections a distinct advance was shown, and a new feature was a large collection of pottery, exhibited by the Egyptian Pottery and Faience Society, many of the pieces being tasteful and artistic in design and colouring. The exhibits of timber-woods showed the great capabilities of the Egyptian soil and climate for their production, and the Finance Ministry is now making experiments in forestry on a considerable scale, and planting out one hundred and ninety thousand young trees of one hundred varieties, all exotic, and chiefly from India. A novelty was seen in a substance called cerosie, of which a French local chemist claims to be the discoverer. It is extracted from the scum which rises to the surface of liquid sugar after the cane is crushed. The resulting substance is stated to possess the qualities of ordinary beeswax, which it resembles in appearance though darker in colour.

Watercress Culture near Paris.—It is interesting to observe that while the culture of watercress received attention in some parts of the Continent before the formation of the Springhead beds, it was not commenced in the vicinity of Paris until after London had begun to receive cresses produced under artificial conditions. According to M. Hericarte de Thury, watercress culture was commenced in the vicinity of Paris in 1811, and from what he tells us in reference to the matter it appears that in the winter of 1809-10, after the peace which followed the second campaign against Austria, M. Cardon, the chief cashier of the Hospitals of the Grand Army (in 1835 mayor of Saint-Leonard, near Senlis), was stationed in the vicinity of Erfurt, capital of High Thuringia. In walking around the suburbs of the city, the ground being covered with snow, he was astonished to observe a ditch of considerable length presenting the most brilliant verdure. He directed his steps towards the spot, curious to know the cause of this species of phenomena, which struck him as so strange at this season, and he recognised, with the greatest astonishment, that the ditches were an immense culture of watercress, resembling the most beautiful carpet, surrounded by ground then white with snow. M. Cardon learned that this crop had been established many years, refreshed by sparkling, bubbling springs of water, on land belonging to the city of Erfurt. This watercress, much esteemed for its purity and superior quality, was sent to the cities on the banks of the Rhine, and as far as Berlin, which is a considerable distance from Erfurt. From here it was that the first lesson on the approved culture of cress reached France. M. Cardon felt what a boon the introduction of such a branch of horticultural industry would be to Paris. He sought a piece of land within a reasonable distance of the capital, watered by a natural spring, and after a long search he found in 1811, at Saint-Leonard, in the valley of Nonette, between Senlis and Chantilly, a site which appeared to offer all the desired conditions. Having seen and studied the process of cultivation at Erfurt to some extent himself, he brought with him two foremen accustomed to cress work, to assist him in the development of the enterprise. In his own interest he had better not have imported strangers into the locality, as these men soon left him to establish rival cress-beds. The Royal Society of Horticulture in France awarded their large silver medal to M. Cardon, in recognition of these valuable services rendered to his country. Since the time of M. Cardon this industry has spread considerably, not only at Saint-Leonard and Saint-Gratien, but all around; notably at Gosse, much nearer to Paris, where large cress-beds were established, and have proved most productive.

Botanical Appointments of interest are:—Dr. Zacharias to be director of the Hamburg Botanic Garden; Dr. Julius Istvánffy to be Professor of Botany at Klausenberg; and Dr. A. Mágóscy-Dietz to be Assistant-Professor of Botany at Budapest.

Gardening Abroad is the subject-matter of an interesting little booklet issued by Messrs. J. Carter and Co., High Holborn, under the title of "Garden Notes for the Colonies and Abroad." The first edition of this work was acquired by one of the Colonial Governments for distribution, so that a certain hall-mark has already been placed upon it. The information compressed into the book will afford valuable hints to colonists and others who have little idea of what vegetables and flowers will grow under certain conditions of heat and moisture and in certain soils. It will also suggest the trial of many subjects to those already established in our Colonies and abroad, while its price—one shilling—places it within the reach of all.

Land Measurement and Surveying are ancient arts, indeed more so than is generally supposed. Professor Hammer has recently directed attention to a Babylonian plan now in the Constantinople Museum. The plan represents a royal estate, and was made 3,000 B.C. An authority on Egyptian archæology goes so far as to name the two surveyors who drew up the plan, but be that as it may, the two series of figures and measurements given show that land surveying was carried on with some amount of accuracy from three to four thousand years B.C.

The New York Botanical Garden is making considerable headway. On the last day of 1897 the ground for the museum was formally broken up, while plans for the ranges of glasshouses have been completed. About 2,900 species of plants, besides large quantities of material for herbarium, library, and museum have been collected during the past year.

SELECT NEW CHRYSANTHEMUMS.

NOW that new varieties of chrysanthemums are increased so rapidly by seed and otherwise in England, as well as upon the Continent and also in America, it is difficult to keep pace with the times without incurring much expense. The time is not far distant when new varieties will be raised in England quite freely and upon scientific rules as to cross fertilisation for a definite object in colour and formation. Hitherto the raising of new varieties has been pretty much a haphazard business. In making a selection of new varieties growers who live far from prominent chrysanthemum centres are much handicapped in not being able to make a personal inspection of the blooms when at their best, or indeed at any time; for such the GARDENERS' MAGAZINE has done good service in the past in disseminating information for the benefit of its readers. With the strict scrutiny practised now by members of floral committees, judges and those responsible for the awarding of certificates to new varieties, a new sort has to be an advance upon older kinds to gain the coveted award. Especially in the incurved secton is it necessary to closely scrutinise additions, as it is a difficult matter to determine to what section they really belong. Too often of late have varieties been first sent out as Japanese incurved when really they have been found, after extended cultivation, to belong to the true incurved, and *vice versa.* If it were possible to have trials of new varieties in the hands of some practical cultivator, so that the members of the Floral Committee of the N.C.S. could inspect them in various stages, better results might be obtained than at present in some instances. Having had opportunities to examine personally many of the new sorts during the past season under various circumstances, I have pleasure in giving a selection of deserving varieties. It cannot be said that the autumn of 1897 was productive of many high-class novelties, indeed, I think fewer really deserving sorts have seldom been put on the market. As usual, the Japanese section heads the list in point of numbers, and as they are the more popular I will name them first.

The section known as Japanese incurved appears to predominate amongst the newer varieties. Belonging to this type are several desirable kinds. Mary Molyneux heads the list, and is an English-raised seedling, perfect in form, and large enough to satisfy the highest aspirations. The colour, rosy peach, is suffused with silver—a pleasing combination. To this a really good companion is Lady Ridgway, which was raised in the Isle of Man several years since. Here we have some peculiarity in colour, for over the amber base of each floret runs a purple suffusion, each floret being tipped with gold when young; the inside of the florets are terra cotta. Yellow-flowering varieties are really well represented by Royal Sovereign, George Foster, and Lovely. In the former we find a rich orange shade in the loosely incurving florets; the last named is quite pale, yet very pleasing. The irregular florets of George Foster are a pure yellow colour. Robert Powell has quite broad florets, terra cotta, shaded bronze, lined and flushed purple. A really good rosy plum-coloured sort is Mdlle. Laurence Zede, which, from the many comments made upon it, is likely to become popular. Those on the look out for a pure lemon-coloured variety would do well to secure Georgina Pitcher. Moor Park is a seedling raised by Mr. Haggart, and shown so well by him at Edinburgh; the reverse is golden-bronze, the inside terra cotta. As is usually the case when a standard variety contributes a sport, it is a good one. This remark applies to the pale primrose offspring from Madame Carnot, and appropriately named Mrs. W. Mease. When I say it possesses all the characteristics of its parent except colour, enough has been said to stamp it as first-class. The introduction of Ella Curtis reminds one forcibly of the original Boule d'Or, sent out in 1886 by Messrs. Veitch as a Japanese introduction. In the present instance the colour is a rich golden-yellow shaded with chestnut and bronze. Another sport of prominence is the ivory-white one from Viviand Morel. Madame Phillippe Rivoire reminds one of Souvenir de Petite Amie, only that the new-comer is so much larger.

Amongst brightly-coloured sorts we have J. Chamberlain, which should be included in the collection of every exhibitor who wishes to be near the top of the list when exhibition time comes round again. Royal Standard, with its broad and flat florets of the deepest crimson, is a good companion to Master H. Tucker, which is a rich dark red with bronze reverse. Amaranth colour is represented by Werther, a promising flat-petalled variety. In the pink-flowered section Mrs. F. A. Bevan stands prominent with its medium-sized curly-tipped florets. Mrs. G. Carpenter, rosy-mauve, is even larger than fully developed blooms of Viviand Morel. Madame G. Bruant, with its irregularly-incurving florets, blush white, suffused with purple, should find many admirers. Mrs. Hunter Little reminds one very much of Criterion; the florets are, perhaps, a trifle narrower, but the rich yellow colouring is pleasing. Admiral Ito is a great favourite with many, and its erect, fluted, and twisted florets are pure yellow. As predicted last year, Lady Hanham has worked its way to the front amongst new varieties; the colour, golden rosy cerise, is pleasing, and when we consider that it is a sport from the ever-popular Viviand Morel that appears to be a sufficient recommendation. James Bidencope was conspicuously shown by Mr. Haggart and others at Edinburgh last season. The colour is telling rosy-amaranth, with silver reverse.

In the incurved section, seldom do we obtain more than half a dozen new varieties yearly. This number has not been exceeded for a long time. Undoubtedly Mdlle. Lucie Faure heads the list. This chrysanthemum was originally sent out as a Japanese incurved, but further trial proved it to be a true incurved. The colour of the pointed, somewhat narrow florets is pure white, while in size nothing is left that is desirable. Madame Ferlat is another of French origin, yet a true incurved; a faint yellow tip is visible on each white floret as it expands, but when fully developed this colour is sometimes replaced with a pink flush. Mrs. N. Molyneux is an English-raised variety from seed, and is full and massive in appearance, and ivory white. In Austin Cannell we have a well-built flower, rich purple, and silver lined. Ernest Cannell, blush pink, base suffused yellow, is a good addition; and so is Lady Isabel, sent out last year; the extra broad florets of this are silvery pink. Mrs. W. C. Egan is presumably a sport from the well-known R. Petfield, which it so much resembles in all respects except colour, which is lighter than in that variety.

Swanmore Park Gardens. E. MOLYNEUX.

FORESTRY IN AUSTRALIA.

THE increasing use of Australian timbers for wood-paving purposes has naturally directed attention to capabilities of the various colonies as permanent sources of supply, the general impression being that in this respect Western Australia takes the lead. This, however, is an erroneous assumption, for, according to Mr. Coghlan, the New South Wales Government Statistician, the Australian mother colony possesses a wealth of timber surpassed by only a few other countries. Its woods are as varied as they are valuable, ranging from the ironbarks, unsurpassed for work requiring hardness and durability, to the kinds suitable for the most delicate specimens of the cabinetmaker's art. Indiscriminate felling has, however, made several kinds comparatively scarce, a frequent experience in newly settled countries, where the leading object of the pioneer residents is almost invariably to get rid of the timber on the lands occupied by them. The necessity of preserving the timber resources of the colony, and preventing the ruthless destruction of the best species of brush and hardwood which was being carried on, principally in the Clarence River district and in the eucalyptus forests on the Murray, led the Government, in 1871, to establish a certain number of forest reserves throughout the colony, in which permission to cut timber, under certain conditions, should be granted upon payment of a fixed fee. Subsequently, in 1875, the office of Forest Ranger was created, and this led to the formation, in March, 1882, of a Forest Conservation Branch, which was attached to the Department of Mines. Seven years later the colony was sub-divided into a number of forest districts. These are frequently inspected by forest rangers, whose duty it is to report on the existing state of the proclaimed reserves, control the operations of licensed timber-getters, receive royalties on the various kinds of timber upon which such dues may be levied, and report upon applications to ringbark trees on Crown lands, whether comprised in forest reserves or otherwise.

In view of the importance of the timber resources of the Colony, the Hon. J. H. Carruthers, Minister for Lands, is preparing a bill, the main feature of which will be the establishment of permanent forestry reserves, where the timber can not only be used as it matures, but where steps can be taken to create a new supply to take the place of the trees which may be felled. This feature of the establishment of permanent reserves is, the Minister says, the chief matter to be considered, and it will apply mainly to the coastal forests, to the red-gum forests on the Murray, and to the ironbark forests all over the Colony. With regard to the pine forests, it is recognized that a different system will have to be adopted, because pine is a timber of rapid growth, and, indeed, in many instances it is nothing more nor less than a noxious weed. In the meantime much has been already effected in the direction indicated. During the last two years about 60,000 acres of red gum, 30,000 acres of pine, and 2,000 acres of coastal forests have been improved by thinning out and destroying the superabundant growths. This work has been carried out with the object of ensuring the maturity of a larger number of trees to the acre, and, by reason of the additional light and air afforded, of their reaching that stage in about two-thirds of the time that would be taken under natural conditions. The cost of the thinning-out operations averages 5s. 8d. per acre in the red gum areas, 4s. 6d. in the pine areas, and 7s. in the coastal areas; and it is estimated that this outlay will return during the next twenty years two or three hundred marketable trees to the acre where the present unimproved average is but four or five. The Forest Conservation branch is charged with the direction of a State forest nursery, which is situated at Gosford, in the beautiful district of Brisbane Water, about fifty miles from Sydney, where the acclimatisation of valuable foreign timber trees, and the conservation of such of the best indigenous species as might otherwise be likely to disappear, are attended to. The area set apart for the nursery is sixty-five acres, of which twenty-five acres are cleared and cultivated. Among the indigenous trees which are raised there may be mentioned tallow-wood, blackbutt, beefwood, silky oak, yellow pine, the best varieties of ironbark, and red cedar, the red cedar seedlings on hand at the close of 1895 numbering about 32,000. Of late, special attention has been paid to the cultivation of the white mulberry, in expectation of a demand for this tree in consequence of the increased interest taken in the cultivation of silk in the colony. It is estimated that there are 28,000 mulberry trees of different varieties, in various stages of growth in the nursery, besides nearly 100,000 exotic trees of economic value.

In addition to reforesting the Crown reserves with the best classes of timber, the State forest nursery distributes specimens among settlers in the sparsely-timbered areas in the western districts of the colony, and supplies them to municipalities, to the trustees of public reserves, and for the improvement of church and school lands and other purposes. Altogether, from 1890 to the end of 1896, over half a million plants were sent out of the nursery, the number for 1896 being 24,769, of which 11,1 were supplied to public bodies and private persons, and 13,649 were placed in reserves and other plantation areas. The number of merchantable plants remaining in the establishment on January 1, 1897, was estimated at 104,040, viz., 21,200 in pots, 17,100 seedlings in boxes, and 65,740 plants open-rooted. The consumption of wattle-bark is very great in this colony, where it is in large demand for tanning purposes. During 1895 80,770 cwt. of wattle-bark were imported, valued at £19,634, nearly 68,000 cwt. of this supply being obtained from Tasmania. It will thus be readily seen that there is room for a large development of the trade in New South Wales. The department has taken steps to prevent the indiscriminate stripping of the bark, and the destruction of the trees, and thus stimulate the trade.

Sydney, N.S.W. JOHN PLUMMER.

EARLY SPRING FLOWERS.

ONE clear indication of the mildness of the season is that hardy plants, in ordinary seasons flowering out of doors at the end of February or March, were in full bloom on January 19, and this in spite of the many dark, foggy days of the previous weeks. There is no doubt the dry, warm summer and following wet autumn had also something to do with the precocity of these plants, the dry weather ripening bulbous plants early, and the early autumn rains starting them sooner than usual into growth.

Among those in flower at Tottenham were Colchicum Bertoloni (C. Stevensi), the Asia Minor form, which is much more robust, hardy, and floriferous than the Algerian form. The bulb is long and rather small, the leaves appearing with the flowers; the latter are globular, bright pink to pure white and carmine-purple. A very pretty plant, the Algerian form differs in the more narrow segments and longer, poorer flowers, flowering as early as November or December, and being less hardy. Cyclamen coum, to which also belong the many forms of Cyclamen Atkinsi, all so easily grown, even in our unfavourable London climate. The difference between the two is the more or less marbled foliage of C. Atkinsi, while in C. coum the leaves are almost of a uniform dark green. They are very free flowering, with purple, rosy, or white flowers, and, like all hardy cyclamen, do best planted shallow in a loamy soil, peat, or leaf-mould, in a partially shaded position; the rockwork border, or, as I saw them growing in gardens near Penryn, Cornwall, planted on slopes on the lawn, suits them well. Crocus Imperati, with its large, bright purple flowers, externally buff-coloured anthers and orange stigma, forms one of the most beautiful of crocus. There is also a pure white form. C. suaveolens differs from C. Imperati in the paler colouring, exterior being striped, and short, stiff foliage. In some seasons this flowers a week earlier than C. Imperati, but this year both flowered at the same time. Crocus Sieberi (C. nivalis), with its bright lilac flowers, is a very strong species, and one that is flowering a month earlier than in former years. C. chrysanthus superbus produces small, bright golden or orange-yellow flowers, with orange stigma and anthers. C. alatavicus, white, exterior striped silvery grey, is a very pretty and distinct species that flowers usually at this time of the year.

Of snowdrops (Galanthus) there are a great many kinds in flower, the most distinct being the following: G. Elwesi robustus, flowers large, white, with distinct, dark, curvate markings on the inner segments, leaves glaucous green, broad, and stiff. G. Elwesi unguiculata has much longer flowers. G. nivalis var. cilicicus is a new early-flowering form, collected on the mountains of Cilicia and sent to this country erroneously as G. Fosteri. It has long, glaucous leaves and white flowers, inner segments marked green. I could not, however, recommend it as a really good plant, especially when comparing it with G. Elwesi, G. Ikariæ, or even G. byzantinus, all of which are superior. G. Perryi is undoubtedly a gem, the flowers are rather small, creamy-white, the ovary being sometimes tinted sulphur. It differs from the closely-allied species G. caucasicus in the broad, pale-green leaves, the leaves of the latter being glaucous green, and very short and stiff peduncle, also exceedingly free habit. G. Perryi was introduced to cultivation by Mr. Ware, of Tottenham, a few years ago. It is of easy culture, but the bulbs should never be allowed to remain out of the ground over a week. G. Ikariæ has large, very broad, bright green leaves, occasionally being pale green, flowers large, white, with green markings on the interior segments. G. Fosteri is somewhat allied to this species, but the leaves are more narrow, flowers smaller and less pure; it is easily grown and flowered, which is not always the case with G. Fosteri. A distinct feature in G. byzantinus is the stiff, plicate foliage; flowers of medium size, white, with green markings on the interior segments; very free and easily grown. G. plicatus has flowers of medium size, but G. latifolius, which is usually as early as the preceding, does not even show flowers yet.

Fritillaria oranensis grows about six to nine inches in height; the leaves are lanceolate-lineata, sessile, flowers one or more, campanulate greenish-yellow striped purple exterior, and tesselated interior. It is a most interesting species, fairly hardy, and the first of fritillarias in bloom. T. Korolkovi is, however, almost as early. Iris stylosa lilacina has bright lilac perianth, rather large, with yellow marking on the lamina of falls and sweetly scented. Iris stylosa alba flowers usually earlier than this plant, while the two darker blue forms, I. stylosa speciosa and I. stylosa Elisabethæ, flower here much later, which may perhaps be owing to the coldness of the Tottenham soil; as the form I. Elisabethæ has already been shown in flower. All forms of Iris stylosa are most desirable on account of their free habit, and they can be grown in any soil provided it is not too damp, which would only encourage growth without producing flowers. To protect the flowers, however, during the winter should sharp frost set in, it is best to have the plants against a wall facing south, or put a frame over them during the winter. They are first-class town plants, as smoke seems to have no influence on leaves or flowers. Iris histrioides, closely resembling Iris reticulata, is giving large bright or dark blue flowers, falls veined white and lilac; these are violet scented. Iris reticulata purpurea (I. Krelagei) has flowers reddish-purple, falls lined yellow; inodorous. The Lenten Roses (Helleborus), in many different shades of purple, greenish-white, white, deep and rosy-purple; flowering during a mild winter as the present, from Christmas till the end of March, are adapted for the margin of the shrubbery, furnishing of cold greenhouses and conservatories, the herbaceous border, and the rockery. Many of the common, more robust growing kinds, are also good town plants. To do them justice they should be planted in partially shaded and sheltered positions, and if once doing well should be left alone.

Of the early spring-flowering Primula denticulata alba, there are now several plants in bloom; this is, of course, remarkably early even for this species, and a severe frost would destroy many of them. Through many years' selection, the once inferior plant has been improved, and has developed a most superior one. The flowers are large, pure white, forming a head, while in the old typical white P. denticulata the flowers were small, very poor, and of a dirty white. It flowers always much earlier than the purple P. denticulata. Primula acaulis cœrulea (Baden-Baden form) is not only much earlier than our common primrose, but it flowers so very freely and is much more robust; in fact, while we find the common primrose loses its leaves during the winter and often dies out entirely owing to fog and smoke, this one keeps its leaves, and its flowers, though paler, seem otherwise not to be any the worse for it. I cannot enough recommend this charming primula to all lovers of hardy flowers. The Snowflakes or leucojums are very early and pretty. L. carpaticum (L. Wagneri) produces peduncles about a foot long, usually two-flowered; flowers campanulate white, perianth segments tipped green; sweet scented. Although in small weak bulbs the difference in size and shape of flower between this and Leucojum vernum is so very slight that none would consider them quite different, yet, when well established and grown, L. carpaticum is at once much stronger, taller, flowers much larger, and nearly every peduncle bears two flowers. L. vernum, when well grown, is sometimes two-flowered, but the whole plant is smaller, weaker, and altogether poorer. Besides, Leucojum carpaticum flowers earlier, and this year the difference in the time of flowering is so great that to-day (January 19), while L. vernum is still under the ground, and only here and there a plant pushing through the soil, L. carpaticum makes a good show close by, in the same heavy damp soil and under the same sunless sky. Leucojum vernum is a very common species in damp and shady places of Germany, Switzerland, and the Austrian Alps. Leucojum carpaticum, or L. Wagneri as some are wanting to call it, is a local Carpathian plant, though sometimes the lower Austrian form is erroneously sold for it. It is the best of the genus Leucojum. Orchis Robertiana—closely allied to that rare British orchid, Orchis fusca—is now producing large greenish purple to dull purple flowers; these are large and sweetly scented. When well developed the plant attains a height of two feet. It is a native of Algeria, and should, on account of its early growth, be planted in a sheltered position. G. REUTHE.

CHRYSANTHEMUM NIVEUS.

THIS favourite show variety has been largely grown here during the past season for producing quantities of flowers in sprays suitable for arranging in vases, and for working into devices and other decorations at Christmas and the new year; and although most of the sorts that have from time to time in the past been recommended as useful for this purpose have been grown here, I have not found one among them that produced such a wealth of pure white flowers, or that opened its blooms in a cool house so easily as this. For flowering late the cuttings should not be inserted until the end of February, and as soon as rooted they must be kept as cool as possible to promote a sturdy growth. Late in May the tops should be taken out of the plants to cause them to throw the necessary number of shoots, which should not be less than six or eight on each plant, according to the size of pot it is intended to grow them in. If likely to be required for vases, pots seven inches in diameter may be used, and in this size some very useful plants may be grown; but to save such close attention to watering, those an inch or two larger are preferable.

When finally potted a neat stake placed to each shoot will keep them secure from breakage, and the pots may be plunged to the rim in coal ashes or other suitable material, which will effect a great saving of labour by way of watering in hot weather. Grown in this way no more stopping of the shoots is required, and the plants will not greatly exceed thirty inches in height, if care is taken that they are not placed under other plants when they are removed to the houses in October. If required in the form of long sprays of bloom, no disbudding will be required, as each shoot, even when grown in a small pot, will bring to perfection several flowers, and as these are produced at intervals of a few inches along the stem, rather than in clusters, and generally open pretty much at one time, this variety has much to recommend it. To obtain large blooms more pot room must be given, and the buds thinned to one on each shoot, and in this way twelve or more good-sized blooms may be grown upon each plant, which will open freely, and of a pure white, even in the dullest weather.

These remarks apply to experience of the variety in the north, where many of the frequently recommended late-flowering sorts do not succeed well, and their flowers when produced are often so weakly in substance as to give but a poor return for the time and labour bestowed upon them. One of the least satisfactory of these is L. Canning, which has been tried both as a yearling and on the second-year system, but in neither case has it proved worth growing here.

Galloway House Gardens, N.B. JAMES DAY.

Drainage of Vine Border.—Failing a natural drain of the right character it is folly to expect good results from vines unless the borders are drained artificially. Considering that the drained border is several degrees warmer than the undrained one, a great point is gained for the welfare of the vine roots. Of course, if the borders are borders inside, so much the better. A raised border with fair drainage and accompanying warmth will be a great inducement for vines to maintain a healthy vigorous condition for a long period. Most growers know how their borders are made, and also, should be aware of the formation of the subsoil or drainage underneath. A clean sand on the top of gravel is good, and gravel over sand is not to be complained of, only such takes more water and also more feeding. Clay under either of these two subsoils will do no harm, at least I have found it answer for at least a dozen years, though possibly in course of time the vines might require root-lifting, *i.e.*, out of the clay. A clay soil for vines will never do, as water does not pass through such quickly. A good test in doubtful borders is to gently dig up the surface and see how much water will pass through in a given time, then dig down for actual proof of the passing of the moisture through the subsoil.—STEPHEN CASTLE, F.R.H.S., *Bottesford Vineries, Notts.*

Some Roses of 1894.

With a view of assisting those who may wish to add recent varieties to their collection, I propose to jot down a few brief notes on some roses of recent introduction, commencing with the year 1894. It would be wearisome to deal with all the new roses that are annually offered, nor would the remarks be of much value, seeing they would only be based upon the highly-toned descriptions which appear in the trade catalogues, especially of continental origin. Therefore, these remarks will chiefly concern those roses which have been grown by us, adding a few varieties that have been seen at the rose exhibitions, or that are well spoken of by some of the trade growers.

Clio, H. P. (William Paul and Son).—Although this rose was not sent out with a great fanfare of trumpets, nor has it been awarded the gold medal of the National Rose Society, yet I think it is one of the best roses of the year. Clio is a robust, strong grower, and free blooming rose. In a cool summer it will probably be found in the front rank, but it is with us hardly full enough to stand a very hot season. In form it is pointed globular and its good shape, size, and depth of petal, make it a handsome flower. It is quite distinct from any other exhibition variety. The colour is white tinted with pink deepening towards the centre. It is useful for exhibition purposes, and the non-exhibitor will find it an acquisition to the garden.

Mrs. Sharman Crawford, H.P. (A. Dickson and Sons).—Colour a beautiful clear rosy pink, quite distinct in shade from any other H.P. It is remarkable for its freedom in flowering and for giving a succession of blooms right through the season. The flowers are of good size but a trifle thin. If grown for exhibition the plant should be well thinned, and the shoots that are left disbudded early, the young growth being carefully kept down, for it is very active, constantly throwing up fresh flowering shoots. It is a somewhat difficult rose to stage by reason of the blooms developing so quickly, especially if the weather is at all hot. It is shown best in cool weather. It was awarded the gold medal of the National Rose Society, probably because of its distinctness of colour. Mr. R. B. Cant in his catalogue describes it as "one of the best roses of recent years," but at present I am not quite prepared, from an exhibition point of view, to wholly endorse this statement. It may be true of it as a decorative rose. In our climate it is inclined to mildew, especially on the second flowering shoots.

Marchioness of Downshire, H.P. (A. Dickson and Sons).—Colour soft pink, shaded rose, cupped, but with too low a centre to be a really good shape, and, like Baroness Rothschild, which it resembles in habit and form, somewhat hollow. In 1896 we had some good flowers of it, and we thought it promising; but the season of 1897 was against it, the early blooms being crippled by the May frosts, which did us much mischief, and the later flowers were damaged by thrip. We only staged one bloom of it during the whole of the exhibition season. From personal experience, which is guided by situation and climate, I do not think it can be termed a first-rate rose, although it won the gold medal of the N.R.S. In some gardens, climates, and soils it may do well, but not with us, and I cannot recommend it.

Clara Watson, H.T. (G. Prince and Sons).—This is one of those roses which are so close to the border line which separates H.T. from teas, that it is not at all clear why it is not classed as a tea. It is decidedly tea-scented, the colour a pearly white with a pale salmon centre, is suggestive of a tea; moreover, it is also in constant flower and has tea wood and foliage. I wonder why it is classed as a hybrid tea! Although the blooms are hardly of sufficient size or substance for exhibition purposes in the general classes against hybrid perpetuals; yet if special classes for hybrid teas were generally introduced in the exhibition schedules, or if it had been sent out as a tea, Clara Watson would be more frequently shown. As a decorative rose it will be found most useful. It is, on the whole, a charming variety. Mr. David R. Williamson states in the "Rosarians' Year Book for 1898" that Clara Watson "is my supreme favourite among the many fine creations of the late Mr. Bennett." Surely this rose was sent out by the late Mr. George Prince, and named after a lady, who with her great skill in setting up the roses so ably assisted him in staging at the rose exhibitions. The rose Clara Watson always brings back to my mind the pleasant memory of the bright and cheerful Miss Watson.

Marquise de Litta, H.T. (Pernet et Ducher).—Carmine rose, large, full cupped, and of perfect form. A useful addition to the exhibition roses by reason of its early flowering. The chief characteristic of the rose is its wonderful blooming capacity. It seems as if when left alone to grow as it pleases it would bloom itself to death, having eight or nine flowers on a stem, following one another in quick succession, and often giving two blooms simultaneously well up to the exhibition standard. The size of the flowers is much improved by disbudding. From an exhibition point of view it is a treacherous rose, quickly expanding in the exhibition tent in hot weather. In the hybrid tea class it holds a good position. For exhibition purposes it is best on maidens. As a decorative or "garden" rose it cannot be too highly recommended.

Duke of York, China (William Paul and Son).—I hope the day is not far distant when all kinds of new roses, whether so called "garden" or "exhibition" roses, shall find their way into the stands for new roses. At present none but exhibition roses practically are staged. This rose is but little known at present by rose exhibitors, not because it is worthless, but because it is essentially a decorative variety. When "garden" roses are exhibited in the same stand with other new roses, such varieties like the Duke of York will find a place. Not growing the rose, I cannot speak of it from experience, but from what I have seen of it, Duke of York is, as indeed all Chinas are, a most useful rose for the garden and house decoration. It has not the form of the exhibition type, but we are not very exacting in this respect with flowers for decoration.

Joseph H. Pemberton.

Late Apples.

Now that the glut is over, one has no difficulty in noticing which are the most useful apples to cultivate, for culinary purposes or dessert, for use from Christmas onward. Of late years it has been rather too much the custom to plant large early show varieties rather than those for general or late use. But where are these fine specimens now? On looking over the fruit-room shelves we find their places vacant, not even one good fruit of the much-lauded Peasgood's Nonsuch is to be found, which, with many, is considered indispensable. A few trees of these fine showy varieties should be planted in every collection where there is room, but planters should be careful not to plant too many of them. A tree or two of each will be quite sufficient, unless they are grown specially for market. As a rule, mid-season apples are almost worthless, while very early and late kinds usually command a good price. During September and October there are so many windfalls that good fruit has to be sacrificed unless sent to the great centres of consumption; for this reason it is not wise to plant many trees of varieties that mature their fruit during the latter month. There is a great difference in the keeping qualities of fruit grown on different soils and situations; and on ground that is cultivated and fed, as against that grown in an orchard with grass beneath. The specimens from the rich cultivated ground may be larger, but they have not the same solidity as those from trees whose roots are growing in the ordinary soil, hence they mature so much earlier. Most people know that large specimen onions contain far more water in proportion to their size than the small bulbs do, their flesh is coarser, and therefore holds more moisture; the same remark applies to apples that have been over-fed.

From this we shall gather that both very early and mid-season varieties should be grown on rich, fertile ground, and liberally supplied with nourishment to induce them to grow as large as possible, and mature early; while the late and long-keeping ones ought not to be fed to any considerable extent, that their flesh may be firmer, and therefore in a better condition to resist the peculiar conditions of the fruit room. That large fruit surcharged with moisture will keep sound longer in a low, dry atmosphere than in a damp one, there can be no doubt, as the moisture given off by the fruit is absorbed before it has time to do any damage, while in the case of hard dry specimens there is but very little to evaporate. Dumelow's Seedling (Wellington) is one of the best cooking apples we have, and though this may be grown to a good size on young trees that are highly fed, such fruit will not keep good for any length of time; in fact, that from trees so treated is not often in a usable condition after Christmas, while that grown on standards in an orchard will keep sound till the end of April if stored in a cool place where the temperature is even. There is not enough attention paid to the storing of these late-keeping kinds, neither is there that care taken in gathering that there ought to be. Instead of throwing them about as one frequently sees, they should be handled as carefully as though they were eggs, and placed at once in the position they are to occupy till required for use.

The old Yorkshire Greening is by no means to be despised, and may be had in good condition till March. The tree is usually an abundant bearer, the fruits both large and of good quality, but they keep far better if grown on orchard trees than from those on cultivated ground. This variety has never once failed here during the last twenty years, though some seasons there are far more than others. Northern Greening, though an old variety, should find a place in every private garden; the fruit is not large, neither has it an attractive appearance, but there are but few long-keeping kinds that cook so well or have a more agreeable flavour. Norfolk Beaufin has for a long time been considered one of the leading late culinary varieties, and there are none of the newer ones that I am acquainted with that will surpass it in this respect. It should, however, be liberally treated where the ground is poor, but by no means be over-fed with a view to obtaining large fruit if it is desired to be kept until late in the season. Royal Russet is another that ought to be grown in every orchard; though not a large apple, its cooking qualities are first-rate, and it will keep in prime condition till April. Schoolmaster should also find a space, as its all-round qualities are good, being a constant cropper, of pleasant flavour, and keeping well.

Turning to dessert sorts, Adam's Pearmain must on no account be overlooked; the fruit is of medium size, handsome, and well flavoured, and though not one of the latest, it will keep good till February. Brownlees Russet is a fine variety, but, like all others of this class should be allowed to hang on the trees as long as possible; the fruits must, however, be protected from tom-tits, as they are very fond of picking holes in them. Claygate Pearmain is also a fine variety; the tree is a constant cropper, fruit of medium size and richly flavoured much in the way of Ribston Pippin. Court Pendu Plat usually has a crop of fruit, and the same may be said of Court of Wick, both of which are very good; the latter, however, cankers very badly on our cold heavy soil. Golden Harvey, Golden Pippin, and Golden Russet are all good, though the former cankers badly here. Lord Burghley is a handsome fine-flavoured variety of first-class quality, and on that account should be planted everywhere that room can be found, as it is a good grower; the same may be said of Mannington Pearmain. The old Nonpareil, when well grown, is a fine variety and a most prolific bearer. Reinette du Canada, when well grown, is also fine; the tree, however, requires but little pruning, as it makes an abundance of fruit buds along the young shoots. Sturmer Pippin is one of the best late-keeping dessert kinds we have; with me it seldom fails to produce a crop of fruit, and though only small it is of excellent quality. Scarlet Nonpareil is also very good, seldom failing to produce a crop of fruit. It must, however, be understood that to have this in the finest condition late in the season the fruit should hang on the trees as long as possible; in fact till the leaves begin to fall, at which time they will part readily from the stalk, and as the weather will be getting cool they will not ripen so rapidly.

Buxted Park Gardens. H. C. Prin

CHRYSANTHEMUMS FOR 1898.

SURELY there is no need for the feeling displayed by Mr. W. H. Lees in his reply to my criticism on his article on new chrysanthemums. I, and other writers, have a perfect right to criticise such and offer our opinion on the same, and if anyone will trouble to refer to my comments on p. 6 they will not find anything that is objectionable, unless it be a presumption on my part to differ in opinion with a member of the Floral Committee of the N.C.S. who has been awarded several big prizes. As to the personal remarks of Mr. Lees I can only say we are not discussing catalogues or manners, and whether I am a more or less modest individual than Mr. Lees cannot be of much interest to anyone. In reply to Mr. Lees' statement that the list was not penned by him for the especial satisfaction of trade growers, I ask him to mention which of the varieties that I have so strongly recommended I have any special interest it. None of them were raised or sent out by my firm, and in the list of novelties I abstained from mentioning any of mine that are to be sent out this season, although certificated by the N.C.S. Mr. Lees says he "only gave those varieties which from my own personal experience and my own personal observation over a lengthy round of shows and other collections appeal to me as the most suitable." Just so, and I did likewise. Mr. Lees wishes us to believe that it is from his position as a member of the Floral Committee that he gathers some of his experience. Strange to note, there are many in his selection of new varieties which have not been noticed by this committee, whilst others that have been certificated this season by the N.C.S. and the R.H.S. are not quoted. This does not say much for the value of certificates. Is Mr. Lees quite sure that he did not consider some trade grower's interest when in his selection of twenty new ones, he placed ten from one grower? Ten from one grower, not including two—Dr. Liebert and Surpasse Amiral—which are likely to prove, next season, superior to many of those quoted, seems to savour a bit of bias.

Now let us discuss the varieties. Pride of Madford, we are assured on p. 808 (1897), has, with snch grand kinds as M. Chenon de Leché, Mrs. J. Lewis, Mutual Friend, Edith Tabor, and others, "been consistently good," and the same writer now informs us he cannot recommend it among the best twenty-four instead of one of the nine whites, because it is too incurved. What are we to understand by "consistently good"? Madame Ad. Chatin I did not compare with Western King; and I, for the sake of argument, may say the latter is not to be compared with Madame Carnot. I still contend, and I know many are of the same opinion, that Madame Ad. Chatin, and many others missing from Mr. Lees' list, are vastly superior to Madame Ad. Moulin. Mons. Hoste and Pride of Exmouth "are of poor colour, and washy and undecided mauve tints are not desirable" we are now told. I maintain that both of these varieties are superior in colour and form to Mrs. W. H. Lees and others in the list of fifty. Lady Saunders, I admit, occasionally comes good, and this is proved by the fact that Mr. Lees had it as a back-row flower in 1896, but where was it in 1897? Ella Curtis, as grown here, was the admiration of all who saw it, and was a truly handsome flower. Mrs. Maling Grant to have proved a failure must have had very poor treatment. It is one of the easiest varieties to grow I know. Mr. Lees maintains that a stand of twenty-four may contain six or seven each of white and yellow. Quite so! But in the selection given there are nine whites, not counting Mrs. W. H. Lees, which is generally shown in this form, dirty white though it be, and but five yellows. I never recommended Mrs. Harman Payne and Ethel Addison; I admit they are of bad type, although Mr. Lees places the sport from the former, Mrs. W. G. Palmer, among the best fifty. Mr. Lees points to the fact that Lady Saunders was in his stand of sixty at the N.C.S. in 1896, and he is thereby justified in including it among the best fifty. I would like to point out that upon looking up the reports of the principal shows I find it mentioned just once, but those varieties which Mr. Lees decries were in nearly all the champion prize stands at all the principal shows. To wit, the £50 and gold medal at Edinburgh, won by Mr. Haggart. Special mention is made among others of Madame Ad. Chatin. £25, forty-eight Japanese, same show and exhibition, Mrs. F. A. Bevan, Mrs. Maling Grant, and Madame Ad. Chatin. We are told these blooms were magnificent. In N.C.S. champion class for forty-eight Japanese, the first prize was won by Mr. Mease, whose variety included Joseph Brooks, Pride of Exmouth, and Lady Hamilton in back row; also showing Julia Scaramanga, Madame G. Henry, Mrs. Blick, and Mons. Hoste. The first prize stand of twelve Japanese at the N.C.S. exhibition with twenty-two competitors, included Madame Gustave Henry and M. Ed. André. At the same show, the first prize for twenty-four Japanese with twenty-four competitors, Mons. Ed. André in back row, and for the only time I here find Madame Ad. Moulin, but in the middle row. Dundee: In the first thirty-six Japanese, Madame Gustave Henry; same show, eighteen Japanese, Mrs. F. A. Bevan, Madame Gustave Henry; and in most of the largest shows were these disparaged varieties, frequently shown together with the other varieties that I have mentioned and omitted by Mr. Lees.

Returning once more to the new varieties, and here Mr. Lees' ruling seems a most peculiar and ambiguous one. Because a variety has been once mentioned by Mr. Lees, is it to be classed among the older varieties? Or are all "new" until this gentleman quotes them? This seems to be the case. Because C. E. Jeffock, which was catalogued in 1896, has not been seen by Mr. Lees until now, is it to be classified as a new variety? Again, because Madame Phillippe Rivoire has not been catalogued by two trade-growers, must it still be considered "new," although several others catalogued it, and hundreds of plants were last season sent to all parts of the kingdom? This variety was catalogued last season by Mr. Davis, although Mr. Lees informs us it is not this. Whether Topaze Orientale will find a place among the incurved, or whether I am justified in criticising Mr. Lees' selection, time will tell.

Exmouth. W. J. GODFREY.

I AM afraid that Mr. Wells's estimate of his own plants and blooms is not always in agreement with that of other people, and it is a pity he has chosen to make a personal matter of my remarks in reference to the Yellow Madame Carnot called G. J. Warren. Personalities are of no interest to readers of the GARDENERS' MAGAZINE, and my notes were not intended in the least degree as a reflection on Mr. Wells's reputation, and it requires a lively stretch of imagination to believe that they were. What I stated was but fair comment on a matter of general interest. This particular variety was exhibited three times before the Floral Committee ere a first-class certificate was awarded, and there is no doubt that the prestige of the parent had as much influence with the committee in the granting of that award as the merits of the blooms shown, which were not so good as many other varieties certificated last season, and, in my opinion would not, on their individual merits, have gained the award.

My points were that over propagation (itself practically a necessity) may have so reduced the vitality of the plants distributed as to account for the very moderate quality of the blooms. It is a well-known fact that this cause is sometimes responsible for failures, and it is more likely to occur in the case of sports than of seedling plants. In the second place there is just the possibility of the sport not inheriting equally the form and vigour of its parent, though I am much inclined to believe that the first named is the real cause in this instance. First sports are most likely to retain all the characteristics of the parent variety except, of course, colour, and deterioration is much more likely to occur in the case of secondary or further removed sports. The question which I am invited to answer in the last paragraph is of no interest to readers in general, but could be answered by the little file of bills which I keep as historical records of new chrysanthemums. I have never yet purchased any at 25s., and in future mean to be extremely careful in obtaining high-priced novelties.

Trent Park Gardens. W. H. LEES.

A FRENCH CHRYSANTHEMUM AUDIT.

SOME of my friends who are members of the N.C.S. will remember being asked to take part in an election of the best fifty chrysanthemums that was organised by the editor of the *Moniteur d'Horticulture* during the past season. Unfortunately many of the lists I distributed were not returned at all, but a considerable number, however, were despatched by me to Paris in time for the election.

The results have recently been published, and it is interesting to find that chrysanthemum growers to the number of 1,057 sent in returns. These growers were resident in England, France, America, Belgium, Switzerland, Italy, Portugal, Austria, Germany, Spain, Turkey, Roumania, Greece, Tunis, and Monaco, a fairly representative body one would think. Out of this abundant testimony to the excellence of Madame Carnot is found in that variety obtaining 1,011 votes, so that, whatever may be the individual opinion of the reader as to the positions occupied by other varieties, there will be little doubt entertained that this celebrated white Japanese is in her proper place.

The proportion of French seedlings is overwhelming, as might be expected, and of these Calvat's occupy a preponderance that leaves all other growers in the shade. It is not my intention to attempt to justify the results, but I have thought those English friends who kindly took part in the election would like to be made acquainted with the result.

C. HARMAN PAYNE.

Lemon Pippin Apple.—Not with much prospect of success this old apple was the other day entered at the Drill Hall in the flavour competition; it is a good keeper, but having rather hard flesh, with a peculiar quince flavour. Such an apple could hardly win in such a competition where so many other better varieties were staged. But the term "lemon" seems to be a comparatively modern one, as more than sixty years ago it was mentioned as having been one hundred years in commerce, and always grown as Quince Apple, though latterly called Lemon Pippin in Kent. The true Lemon Pippin of that day was a fruit ripening in October and November, bright yellow in colour, round in shape, and rather flattened at the ends, flesh crisp and juicy. That description differs materially from what is applicable to the variety now grown as Lemon Pippin. However, we have plenty of better apples than are either of these named. Of a list of one hundred and thirty varieties in 1834, not more than twenty-five are now commonly grown.—A. D.

LÆLIA BRESEIS.

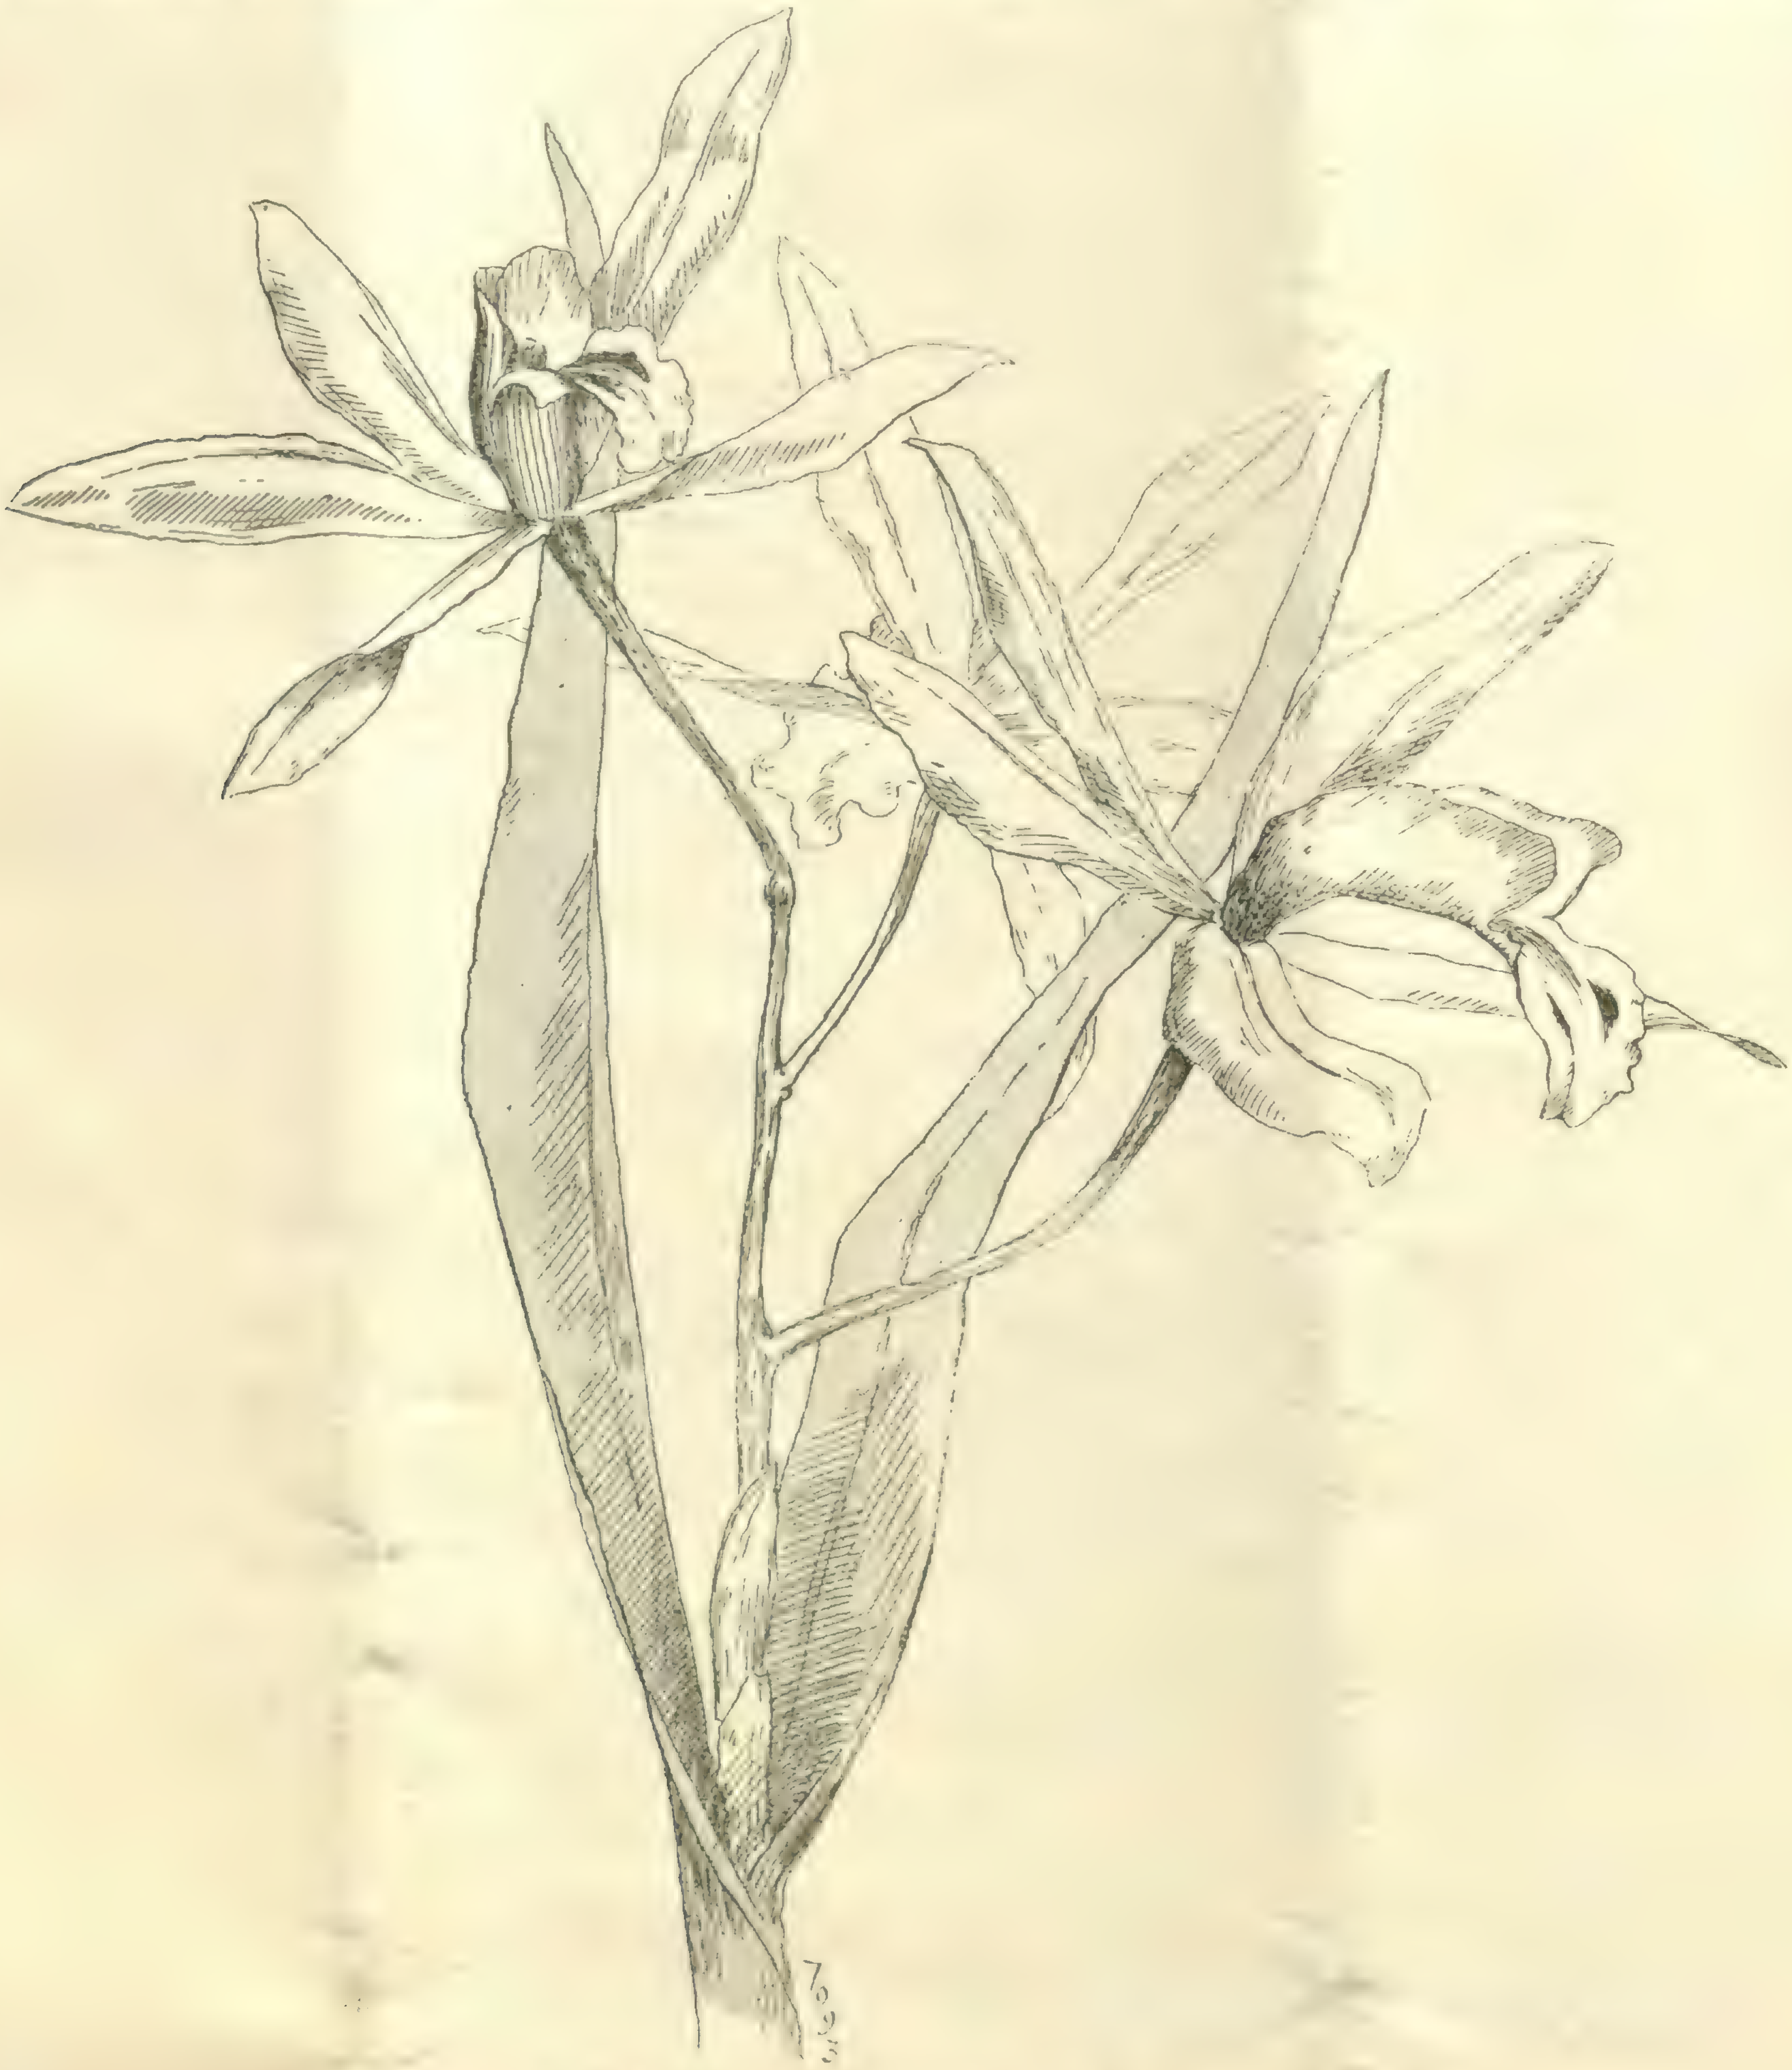
A most distinct and attractive orchid is the new hybrid Lælia Breseis, raised by Mr. James Douglas, Edenside, Bookham, and exhibited by him at a meeting of the Royal Horticultural Society, held December 14, 1897. The Orchid Committee considered it worthy an award of merit. It is a novel hybrid, obtained by crossing the orange-red Lælia harpophylla with the handsome white and purple flowered L. purpurata. The former, or seed parent, has created the most influence, the habit of the plant, shape and colour of the flowers, reminding one mostly of L. harpophylla. The sepals and petals are pale orange, lip whitish, narrow, the side lobes clasping over the column; apical lobe white with two purple blotches. The edges of the front lobe are considerably crimped and waved. The accompanying illustration gives a fair idea of the size and shape of the flowers.

With respect to Lælia Breseis, Mr. J. Douglas writes: "This garden hybrid was produced by crossing Lælia harpophylla with the pollen of L. purpurata, but the pollen parent does not seem to have exerted much influence upon the colour or form of the flowers, or even upon the character of the plant. It is, however, evident that the cross has been effected, for both plant and flower differ from the seed parent. If possible, I always make orchid crosses both ways, but one cannot always be sure of obtaining plants in each case; in this instance, the reverse cross, to L. Breseis that is, seed from L. purpurata, failed to vegetate. Blooms of Cattleya labiata have been fertilised with the pollen of L. Breseis, but unfortunately the lifetime of one man is not long enough for carrying to a conclusion many experiments of this kind. The flowers fertilised will probably ripen their seed pods towards the end of the present year; the seed may vegetate in from six to twelve months more, and, if by a fortunate chance any of them live to flower, such an occurrence will happen about 1910 or 1912, or may be a few years later than that. Sometimes a period of nineteen years elapses between the time of sowing the seed of a cattleya and the period of flower production."

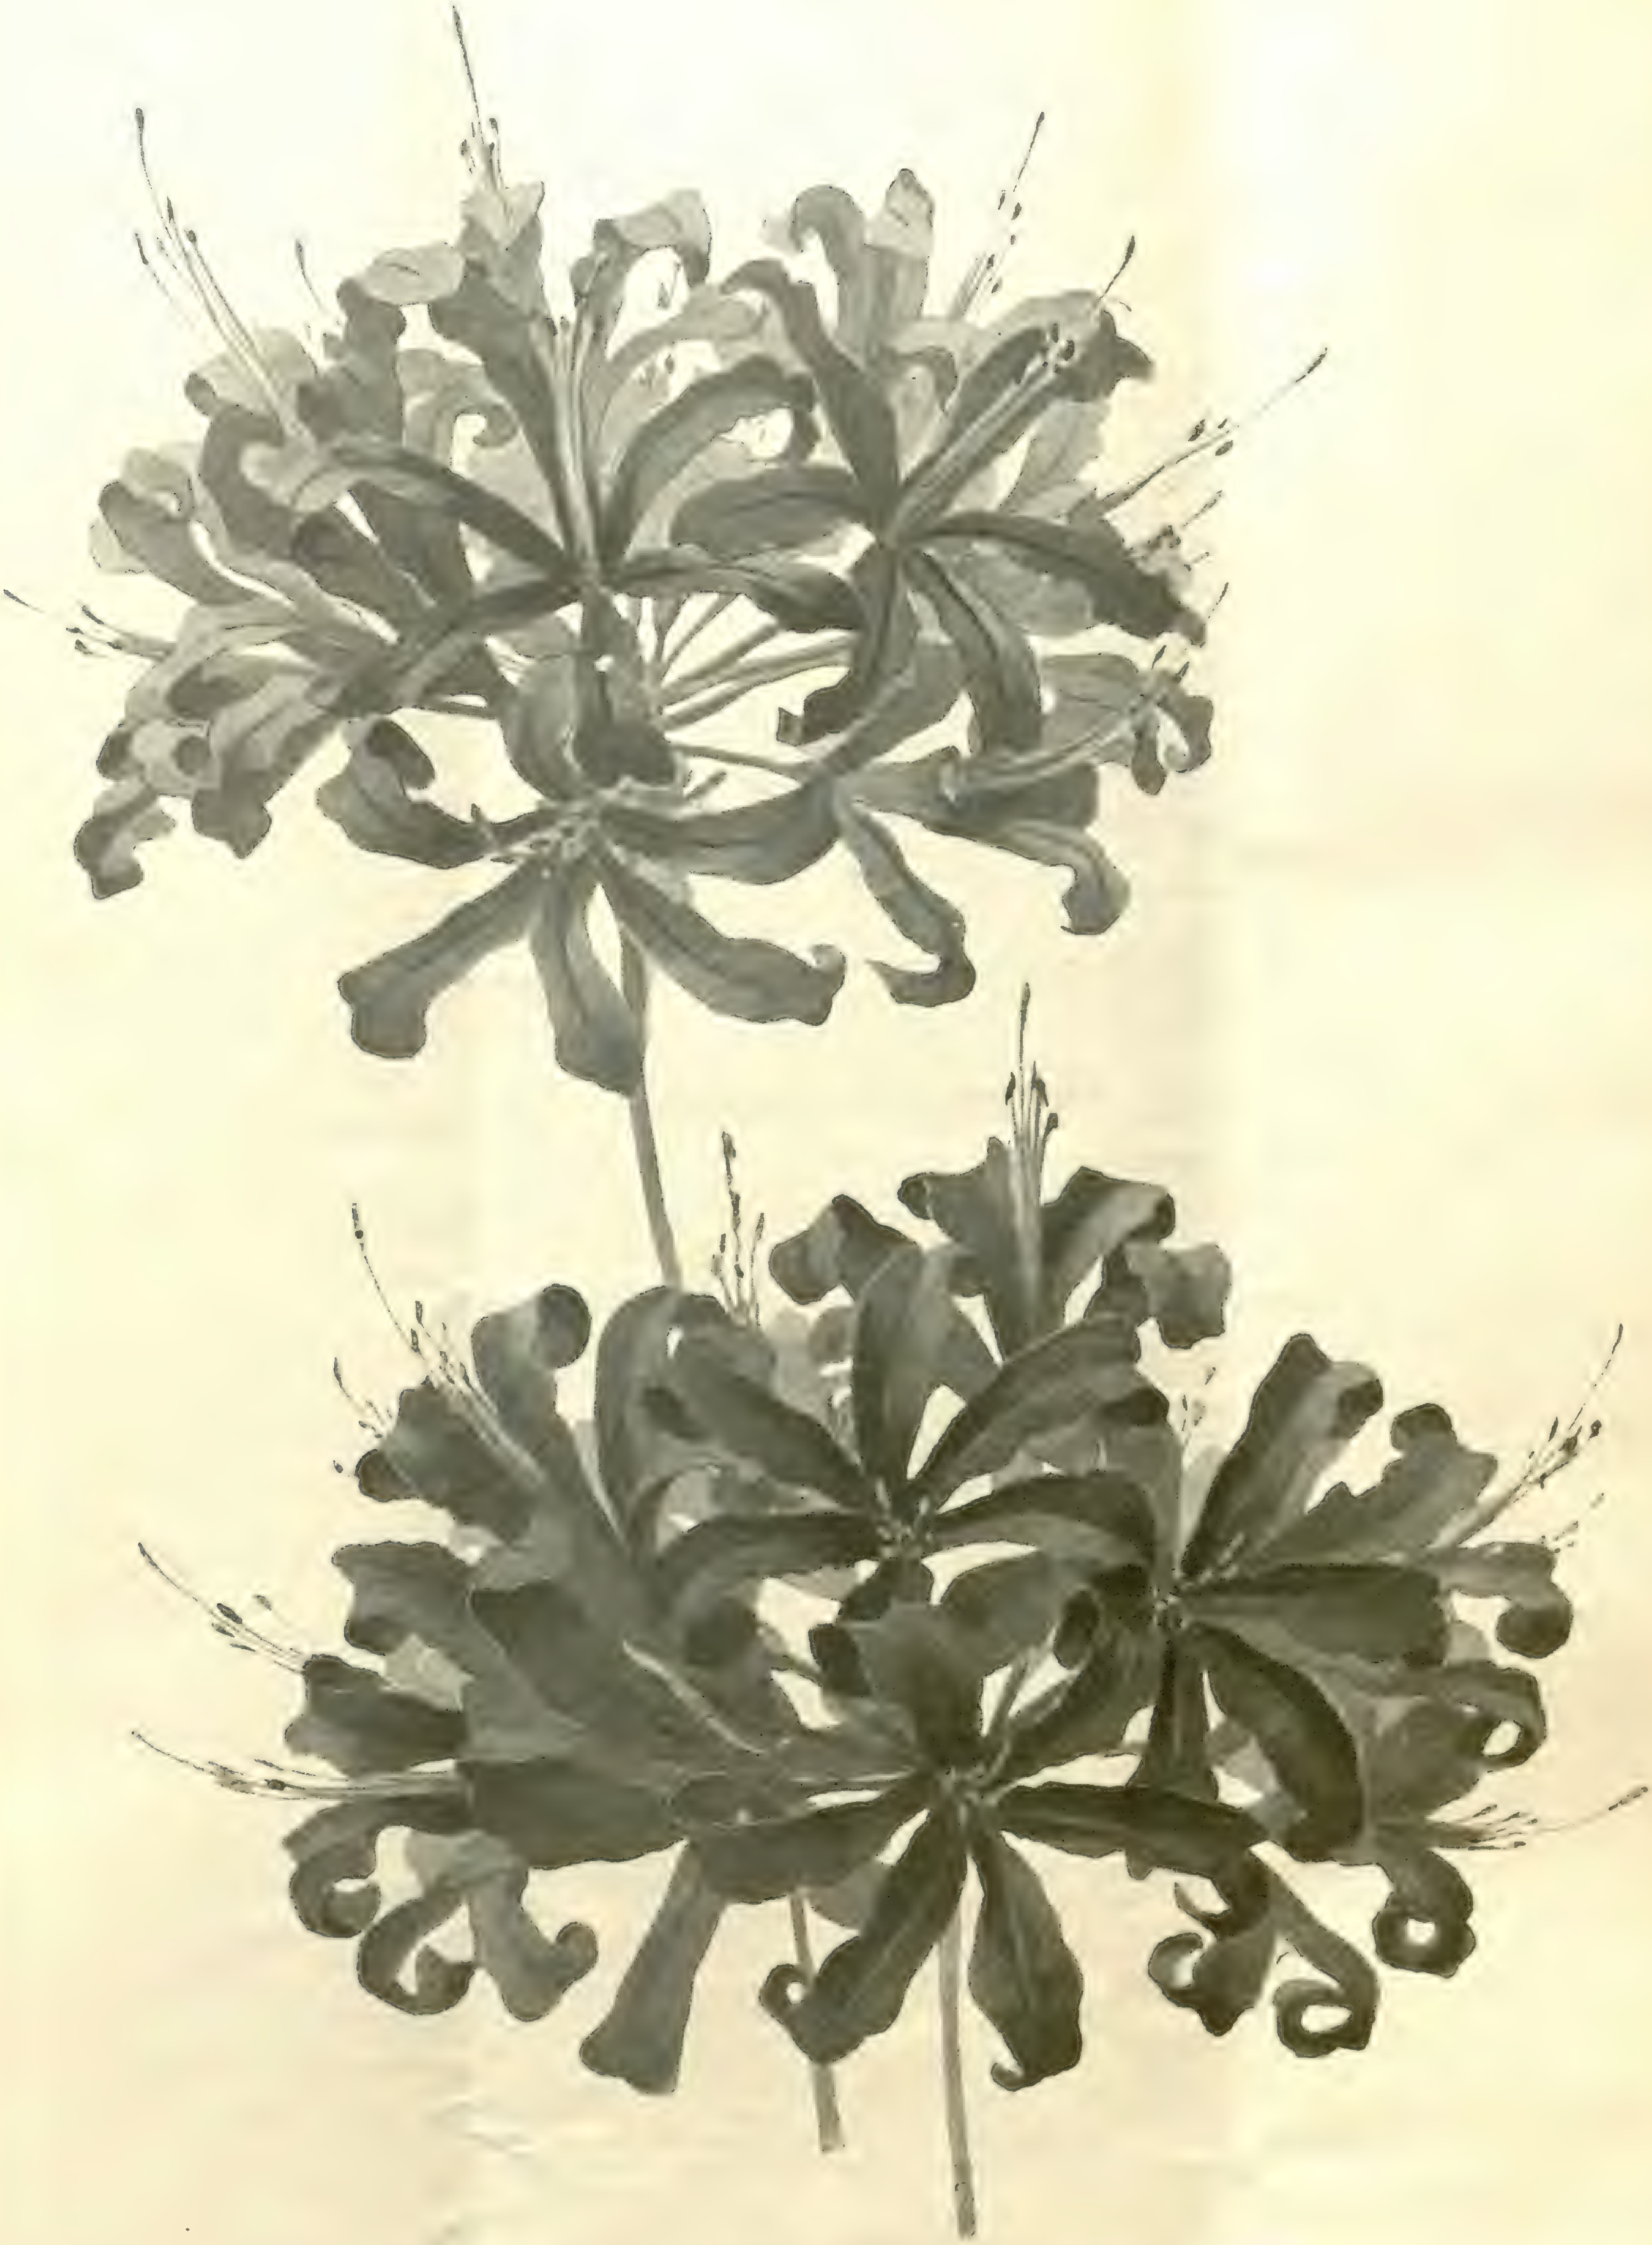
NEW NERINES.

It has been said time after time by those well qualified to speak that there is no more pleasing hobby for a gardener, either professional or amateur, than the improvement, so far as time and circumstances permit, of one plant or class of plants. It might also be added that scarcely anything can more advance horticulture than this. Almost every garden plant of general usefulness has been improved and brought to its present state of perfection by the careful hybridising, cross fertilisation, or selection carried on with great patience and perseverance by one or more individuals or firms. The greatest difficulty is usually to know what to commence upon, but a little careful consideration will soon show that there is abundant room for improvement in very many subjects.

It is highly probable that when Mr. H. J. Elwes, of Colesbourne, Andoversford, Gloucester, commenced his work of improving nerines he had little hope that such a large measure of success would attend his efforts as he has already realised. Although there are several species of nerines in cultivation, scarcely any others than N. sarniensis and N. curvifolia Fothergilli are known to the majority of gardeners. The colours found in the various members of the genus are scarlet in several shades, crimson, red, pink, rose, and white. In some cases, however, the flowers are small and flimsy, segments narrow, the umbels are small and loose, and the habit of the plant weak. So in the production of new and thoroughly useful garden forms, not a few difficulties would present themselves, even after the initial one of obtaining plants of the various species and hybrids had been surmounted. About fifteen distinct hybrids have been raised and recorded, but little is known of the majority of them beyond their parentage. Probably the first hybrid nerine raised was N. Mitchamiæ, a hybrid between N. undulata pollenised with N. curvifolia, and raised by Dean Herbert at Spofforth in 1815. Other crosses were made by Herbert, and, as showing the patience necessary with this genus, he states that "Seedlings of undulata flower when about three years old; the strongest of the mules blew at four years; but



LÆLIA BRESEIS. (Flowers orange and white.)



NEW NERINES.

LADY LLEWELLYN. (Flowers deep carmine.) LADY LUCY HICKS BEACH. (Flowers intense and glowing crimson.)

seedlings of curvifolia seem not to flower till they are eight or nine years old."

From the robust habit, stout peduncles, and full umbels of large flowers that Mr. Elwes' seedlings show, one judges that Nerine curvifolia or its garden form, N. Fothergilli major, has been extensively used as a parent. The colours, too, lead to this conclusion, for though there is a wide difference between the colour limits of the plants yet exhibited there is a preponderance of crimson and scarlet shades. At the R.H.S. meeting of October 26 last, Mr. Elwes staged a charming exhibit of nerines in flower, showing some beautiful new seedling varieties as well as some hybrids. Among the latter were N. amabilis, a cross between N. pudica and N. humilis; N. excellens, a cross between N. flexuosa and N. humilis major; and N. roseo-crispa, a hybrid between N. undulata and N. flexuosa. Species were represented by N. flexuosa, N. undulata, and N. Fothergilli. The stamp of first-rate cultivation was seen on all alike, species, hybrids and varieties, and the plants reflected much credit upon Mr. Lane, Mr. Elwes' gardener.

Eight of the new seedling varieties raised by Mr. Elwes were placed before the Floral Committee, and it argues well for their beauty and distinctness that seven were granted awards of merit. These were: N. Lady Lawrence, salmon-red, fine truss; N. Lady Bromley, carmine, with a rosy-purple stripe down the centre of each segment; N. Lady Mary Shelley, a lovely pale pink variety, very distinct and with broad reflexing segments; Lady Lucy Hicks Beach, a superb form, having a large, full truss of bold flowers, that are of an intense and glowing crimson hue; Lady Llewellyn, very deep carmine, a lovely shade, flowers large, and segments very broad. The two latter varieties are figured in the present issue, and though in black and white it is possible to indicate the proportions and shape of the flowers and trusses, it is not possible to give an adequate idea of the living glowing colours; an oil painting would scarcely give them full value. The other varieties gaining awards were Lady Dorrington, with broad, white segments, having a pink line along the centre of each; and Countess Bathurst, white, blush tinted, and with a deep pink stripe at the base of each segment. We believe that Mr. Elwes has still other seedlings with which to surprise us on some future occasion, but whether this be so or not he has given nerine culture the fillip it needed, and vastly improved the genus from a horticultural point of view.

PREPARATION OF THE LAND FOR EXHIBITION VEGETABLES.

ANYONE wishing to excel in the cultivation of vegetables, either for exhibition or for table, must lose no time at the commencement of the new year in making suitable preparations. It is a good idea to make a rough plan of the kitchen garden, and indicate on it the plots intended for the production of certain vegetables. Each plot should be measured, marked out, and labelled, taking care to change the ground for most crops as much as possible. The land that has been occupied with celery should be trenched over, but not manured, and this site will be an ideal spot for the production of most kinds of roots, such as: Beetroot, carrots, parsnips, salsafy, scozonera, turnips, chicory, potatos, &c. Ground intended for peas, beans of all kinds, cauliflowers, onions, and such like, should be heavily manured and trenched. At this season one has to be guided, to a great extent, by the condition of the weather and the nature of the land. Thus, on light, well-drained soils, trenching should be pushed forward with the least psssible delay. On the other hand, anyone who has to deal with stiff, wet soil, should postpone digging and trenching as long as possible, and the end of February, or early March, will be quite early enough to make a commencement. Take advantage of all dry frosty weather for wheeling out manures and other fertilisers, and indeed all kinds of work that can be done to relieve the strain that will have to be encountered later on; such as pruning of bush and other fruit trees, preparing pea and bean stakes, making labels of different lengths, which should be tied up in bundles ready for use.

The soil and manure yards should not escape attention at this season, I have heard it remarked by an old man who had been a most successful horticulturist, "Show me the compost yard of the gardener, and I will tell you if he is a good man or not," and I believe there is a lot in this. A good yard full of various soils, manures, &c., neatly stacked, clean, and well arranged, is to my mind one of the most important departments in the garden. Every particle of garden refuse should be kept burnt up, as the ashes are of the utmost value in the kitchen garden. Boxes should be examined and repaired, and new ones made if wanted. Old hot-beds that have done service during the past year should be turned over into a tidy heap, which will prove valuable for many purposes. Fermenting material should be prepared for new ones in the way of long stable litter and good sound leaves, such as oak, Spanish chestnut, and beech. One part of stable litter to three of leaves is generally a safe quantity to use, and these should be turned two or three times before building them together. Many early crops of potatos, asparagus, carrots, &c., are spoilt by overheating. All brick pits intended for the production of vegetables should be cleared out and thoroughly cleaned.

Making out the seed order is a most important part in the programme. The observant and painstaking gardener will have carefully made notes during the past year of novelties that have come under his notice. But great care should be exercised in making way for new kinds to replace reliable standard varieties. At the same time it is well to give a fair trial to some of the new kinds offered each year by the seedsmen, using small quantities of seed and giving precisely the same conditions as the tried kinds receive, for only in this way can their respective merits be fairly determined.

Wilks, Miss Willmott.

The Narcissus Committee will meet in the Drill Hall, James Street, Victoria Street, Westminster, on the following dates, at 12 o'clock, noon, viz., March 22, April 12, and April 26, 1898.

SCHIYOSTYLIS COCCINEA.

IT is seldom that a season passes without the good qualities of this plant being referred to, and, as an easily grown and free-flowering subject for the winter months, too much can scarcely be said in its favour. As a pot plant it is very suitable when in bloom, either for placing in a vase for room decoration, or for arranging with other plants in the conservatory, where the tall scarlet spikes rising above the deep green foliage give a touch of colour that is very pleasing. For this purpose the plants are best grown in the open through the summer, and if turned out of the pots in April, and divided, selecting only the strongest bulbs, and placing them about fifteen inches apart in moderately rich soil, fully exposed to the sun, strong clumps will be formed by the autumn, when they may be lifted and potted before severe frost sets in; subsequently they only require the protection of a cool house or frame until the flower spikes appear.

But it is when treated as a hardy plant that I would like to direct the attention of those who have not grown it, to Schiyostylis coccinea, and where a wall or building exists some of these plants planted at its base, even under the trained branches of fruit trees, will often prove more profitable than any other plant, and in mild winters like the present quantities of bloom may be gathered, while the effect produced by the ever-expanding flowers, when all else is bare, is ample reward for the little trouble required for their successful cultivation. Several clumps were planted near the base of a west wall here last spring, and for some weeks past these have given us a nice lot of flowers, and plenty more ready to open. To be successful with these it is necessary to divide the clumps every year, otherwise so many young shoots start that the flower-producing properties of the plants are weakened thereby. Few plants are more easily cultivated, as after planting or replanting but little attention is needed, beyond keeping them clear of weeds, and an occasional watering in very dry weather. In the open border the plant will sometimes bloom very freely, but as very much depends upon the weather at the time, the flowers cannot be depended upon to attain their full development.

Galloway House Gardens, N.B. JAMES DAY.

EFFECTS OF THE TROPICAL SUMMERS OF 1896-97 ON THE FRUIT CROPS.

THE following is the text of the paper read by Mr. George Bunyard, V.M.H., at the monthly conversazione of the Horticultural Club, on the influence of the weather of the past two summers on the fruit crops :—

In reviewing the many-sided effects of the tropical summers of 1896-97, the facts range themselves as favourable and unfavourable. The tropical heat, combined with drying winds, and that general absence of rain during the spring months of the period under notice, dried the soil to an unusual extent ; and although in 1896 abundant autumnal rains fell, in 1897 the months of September and October were the driest known for years. The effect of the heavy rains of the autumn of 1896 was felt in the activity of the sap and the adhesion of foliage on fruit trees rather later than usual, and consequently the trees did not have that rest which is as necessary for the vegetable world as for the animal creation ; and we agree with Mr. R. D. Blackmore that the general failure of fruit crops in the spring of 1897 was largely due to that cause.

The want of power in the trees themselves to lay up that necessary nutriment, and ability to perfect embryo fruit-buds, was arrested at a critical period, and, as reported in the gardening papers, many cases of imperfect blossoms were noted in fruits, and doubtless many more facts would have been discovered had they been suspected and looked for. To outward appearance the blossoms were perfect, the corollas being bold, as usual ; but in many individuals either stamens or pistils were wanting, and no doubt also the upper or fruit-nourishing roots suffered from the want of surface moisture, and thus were prevented from doing their work ; while lower anchor-roots struck deeper and deeper to gain moisture and sustenance for the development of the tree, making the subject less fertile, and adding gross wood to all garden trees, and thus trees were found to require root-pruning more than usual to restore that relative balance of fruit and wood producing power which a well-managed fruit tree should exhibit.

In orchards (especially among young trees) the want of fruit was a distinct benefit, as they are then enabled to form vigorous trees before starting to crop, and a foundation is thus laid for full development and after-success ; as if a young orchard tree commences to crop in its earlier stages, its after-growth is checked for years, and in the future such checked trees produce pecks where bushels of fruit should be garnered.

In the dry autumn of 1897 matters were different, and the glorious and varied colours of the foliage on cherries, peaches, and nectarines, and the fine russet-brown of the apple foliage, and the golden plum leaves, leads us to infer that Nature's work has been well and truly done, and with a fair spring a good all-round crop may be anticipated in 1898. Although from a nurseryman's point of view the shorter and stouter growth fruit trees made in 1896-97 meant some loss and extra expense in staking for standard trees, &c., still the growers cannot fail to be great gainers in having the wood of fruit trees well ripened, hardened, and consolidated for future benefit, as heavy frosts tell much less severely on such perfected trees. If this is felt in the south, how much more must it benefit planters who live in the midland and northern counties ! The handsome fruit shown by Mr. Day, from Galloway House Gardens, and the grand pears from Mr. Divers, Belvoir Castle Gardens, sent to the Royal Horticultural Society, bear out this fully.

The fruit crop of the Jubilee year, 1897, will be remembered for its remarkably high colour and development more than for great size. Many examples submitted to us have been beautiful beyond all former years ; for example, crimson Blenheim Pippin, Warner's King, and other green apples with scarlet flushes on the sunny side ; and Doyenne du Comice and other pears with lovely red cheeks ; while many Russets lost their character and came out with golden skins, only broken here and there with russet. Many of the less hardy apples as Lord Suffield, Ribston, King of Pippins ; and Glout Morçeau, Bergamot d'Esperen, Gansel's Bergamot, and other pears have been so handsome and good that planters have called for them freeely, forgetting that they are not to be relied upon (as a rule) for freedom from canker, or quality. Their extra good appearance, flavour, &c., point a moral, and doubtless we ought to place these and similar good but variable apples on walls or in warmer places. Apples of the type of American Mother, Melon, Scarlet Nonpareil, Allen's Everlasting, Duke of Devonshire, Sturmer Pippin, with those that do not always ripen well, as Calville Blanc, Boston Russet, Calville Rouge, Chatley's Kernel, Reinette du Canada, Dutch Mignonne apples, with Beurré Diel, Bergamot d'Esperen, Olivier des Serres, Beurré Rance, Beurré Baltet, President Osmonville, Easter Beurré, Zéphirin Grégoire, &c., pears, would not be out of place on many walls which are well situated, and now devoted to a doubtful crop of peaches or nectarines, especially those old walls, unpointed and full of nail-holes, one often sees in ancestral gardens, where choice pears and apples would flourish and give good results. The extended use of large and handsome apples for decoration should lead growers to place Peasgoods Nonsuch, Buckingham, Belle de Pontoise, the Queen, King of Tomkins County, Twenty Ounce, Gascoigne's Seedling, &c., on walls for this purpose.

One special feature of the 1897 fruit crops was the general success of the British-raised varieties, such as Nonpareil, Northern Greening, Wyken Pippin, Blenheim Pippin, Devonshire Quarrenden, Yellow Ingestre, Stirling Castle, Wellington, Ecklinville, Kerry Pippin, Keswick Collin, Winter Queening, Nanny, Hormead's, Lane's Prince Albert, among apples ; and Hessel, Althorp Crassane, Hacon's Incomparable, Bishop's Thumb, Pitmaston Duchess, Crawford's, Aston Town, Eyewood, and Knight's Monarch, among pears, causing a demand to arise for trees of many old and superseded kinds, which for market purposes are yet valuable. The general crops on the Codlins and early apples and pears need only to be noted to state the fact that such kinds have time to recover themselves after the fruit is gathered, and to prove regularly fertile.

Exceptional prices have been made of some fruits. In our district, Devonshire Quarrenden, Ingestre, and Ribston apples (one grower selling one hundred bushels of the latter as gathered at 14s. 6d. per bushel), while Cox's Orange Pippins made up to 25s. per bushel retail ; and Wellingtons, with a peach-like colour, made 10s. 6d. wholesale. As might be expected, the heat and drought has caused all late pears to ripen months before their usual season, and by the time this is in print many fruit-rooms will scarcely have a pear in them ; at present Olivier des Serres and Beurré de Joughe with a few Easter Beurré from open trees are all we possess. But we are inclined to think thorough ripening will allow us to keep apples as late as usual, while they will certainly not be so large examples—in short, beauty will compensate for mere size.

Perhaps no outside fruit felt the grand weather of 1896-97 more than peaches and nectarines on walls. The trees made that reddish wood so dear to the cultivator's eye, and the crop set well ; and the fruit where the trees were copiously watered, grew out to a fine size, and coloured to perfection, raising the almost lost hopes of many old gardeners to encourage them to persevere in their open-wall cultivation ; those who had late peaches made long prices, as the fruit under glass was forwarded by the heat, and thus made a market for the outdoor crop. Peaches and nectarines are yearly more in demand. We attribute the failure of the plum crop to the causes already named, which by their surface-rooting nature, would naturally be affected more than deeper-rooting fruits.

We cannot refrain from again cautioning gardeners from relying on a few varieties for an annual crop ; and the best kinds for quality should be planted in various positions to ensure a return, and also to lengthen the season of each kind. Market-growers naturally go in for the sorts favoured by the public, but we are inclined to think many less-known but reliable croppers should be introduced. Strawberries, raspberries, and bush-fruits generally cropped where good deep cultivation was practised.

In conclusion, it is evident that cultivators should do in all in their power to utilise all the sunshine possible, and the protection they possess added to careful thinning of boughs and fruit, and by giving liberal encouragement to the trees that crop, and not over-stimulating those that are barren.

THE R.H.S. COMMITTEES' AWARDS.

AS you have so pointedly referred to this subject, which has been again, and in precisely similar language, raised in the report of the council of the Royal Horticultural Society this year, I offer no excuse for also referring to it. I observe that the total number of awards of medals and certificates made in 1896 was 948, and last year 1,008 ; the Floral Committee's were in the former year 463, and last year 502, an increase of 39 ; the Fruit Committee gave in the previous year 102, and last year 119, an increase of 17 ; and the Orchid Committee 303 the first year and 251 last year, showing a drop of 52. The most remarkable figures are those of the Narcissus Committee, which gave four only in 1896 and no less than 20 last year. Now there has been over the present year an increase of eight gold medals, but these are, it is well known, purely honorary awards, and may well be omitted. They have always been bestowed on objects of special excellence, and that being so, it is a question for consideration whether the exhibits do not materially enhance the value and interest of the meetings. Of course, if such awards are not made the exhibits will in future be absent. There has been, however, great increase in the awards of the silver-gilt Flora medal, granted solely by the Floral Committee, an increase of 31 ; whilst the silver-gilt Knightian medal, the Fruit Committee's corresponding medal, has been awarded 16 times only. Then the silver Flora is given by the Floral Committee 79 times, and the silver Banksian 81, or a total of 160 ; whilst the Fruit Committee awarded the corresponding medals 38 times only. Whilst there is a reduction of first-class certificates of merit from 84 in 1896 to 54 in 1897, there has been a trifling increase in awards of merit by the Fruit Committee from 23 to 35, and that is practically all. If the Council had adopted my proposal made and carried at the Fruit Committee, that no award of merit or F.C.C. be granted except by a majority of two-thirds of the members present, there would all round be found a material reduction in these awards. But the Council blow hot and cold. They deprecate granting medals and other awards, the primary causes of such good shows at the Drill Hall, yet in a later paragraph laud the shows and exhibitions in warm terms. Surely that is inconsistent ? That there has been a great increase in interest and attractiveness in the meetings there can be no doubt, due largely to the awards made and increased confidence in the honour, and integrity of the committees. But after all, no award can be made by the committees. They are purely recommendations to the Council ; and if the committees are wrong in their acts of recommendation, the Council are *particeps criminis* in sanctioning the awards thus recommended. Why does not the Council exercise its own powers, or does it fear to offend the committees ? The least the Council can do is not to make complaints of the nature here criticised, but to formulate some regulations as to the committees' awards which shall result in a material reduction of them. Suppose it were to begin as thus : " No member of the Council or any firm of which a member may be a partner, shall receive awards for exhibits." That would be beginning at home ; but is it likely for one moment so drastic a proposal would be adopted ? Not a bit. Then who is to give the committee in this matter light and leading. Now I turn again to the analysis of awards presented in last year's report, and the present one. In the former the provincial show deputations made a total of 75 awards, but last season they visited one show only, and made 36, or just about the same proportion. Well, the council cannot claim much credit there. Then again, the total of 1,008 awards is now swollen by the introduction of a new column. Last year's table shows the award by the Scientific Committee. That body disappears from the new table, and its place is taken by " Medal awards, other than bronze," of 80, to affiliated societies, with which the committees have nothing to do ; so that if 80 be deducted from the total of 1,008, it leaves 928, or a reduction on the previous total of 20 ; therefore, it is evident that on the whole there has been material reduction, and that the committees are little open to animadversion. I hope this matter will be fully dealt with by the president at the annual meeting.

A D.

A USEFUL ORCHID STAND.

MOST orchid growers who have to deal with plants placed over a close wooden stage upon which has been scattered a layer of shingle, cinders, coke broken small or similar material, know what it is to have to deal with a troublesome fungus which forms in the decaying wood and runs up into the orchid pot. I invert flower pots, and on each one a pot containing an orchid is placed. The other day I turned up some of these, and was horrified to find the fungus had entirely covered the insides of the inverted pots with a cobwebby substance, and had sent snow white threads through the base and into the pot in which the orchid was growing, and in several instances had passed up amongst the orchid roots. While considering what had better be done to stop the progress of the fungus amongst the orchid roots and prevent it in future from attacking the plants at all, there came from Mr. William Murray, of Oakwood Gardens, Wylam-on-Tyne, a series of stands made of stout wire in the form of a flower-pot ; they answer the same purpose as the inverted pot, no fungus can lay hold of the stands, and they have a much better appearance than the flower pots. I could but remark that here was the very thing needed to prevent the fungus reaahing the orchid roots, giving us at the same time a much neater stand for the plants. The old saying is exemplified " Necessity is the mother of invention." If Mr. Murray had not had any fungus to deal with, he probably would never have thought of this useful little stand.

J. DOUGLAS.

WORK FOR THE WEEK.

WARM ORCHIDS.

AMONG recent introductions Dendrobium phalænopsis Schroderianum claims to be of the greatest value, especially where floral decorations are largely carried out; for table decoration there are few flowers to equal it, and for a lady's spray it suits admirably. In its principal season of flowering, and where a good stock is grown it makes a fine display in the orchid houses. The general opinion is, that this particular species deteriorates; whether this is so or not, we can point to plants of ten years' standing which are still healthy and promise well for a long life. Dendrobium bigibbum, which is entirely of the same nature, has often been a source of anxiety to orchid growers; for the first few years it flourishes, but in course of time gradually decreases in strength and ultimately finds its way to the fire. These dendrobes should have a long season of rest and should be kept at a temperature of 60 degrees and allowed sufficient moisture to keep the bulbs plump; water only when necessary, and give special attention to ventilation. The bottom ventilators must be left open night and day when the weather is favourable, in order to keep the atmosphere as sweet as possible; guard against draughts and fluctuations of temperature. D. formosum giganteum is another grand and favourite dendrobe, but like the former is not a good grower; this may be treated in the same way. D. Deari delights in a warm shady corner, such as the phalænopsis house affords, and enjoys being syringed once a day, weather and temperature permitting; keep the plants moist at the roots, and free from scale; if this pest makes its appearance give a washing with a solution, taking care not to injure the leaves. D. Ainsworthi and varieties that were removed to a warmer house in order to bring them on gradually may now be given still warmer quarters, and be sprayed slightly over each morning and not allowed to become dry at the roots, otherwise the spikes will go yellow and finally die. Those that are resting must be kept at 55 degrees at night, allowing the temperature to rise a few degrees in the day time; these may be slightly syringed about once a week on suitable occasions. Still allow the plants to rest, but simply to refresh them thus while in a state of dormancy; a few more of the most forward may be put into a warmer house as before, in order to keep up the display.

Cattleya Trianæ and its varieties are now coming into flower, and may be removed. together with Lælia anceps, cypripediums, &c., to the flowering house, and kept in a temperature of about 55 degrees. Fumigate slightly if fly appears. The phalænopsis will now be coming into flower, so prepare neat sticks to support the spikes, and intermix P. amabilis with P. Schilleriana to produce a fine effect. Put down Magic Paste for beetles, otherwise you will have perforated flowers and leaves, and the roots, which are so valuable, will be eaten off. Sobralias and cymbidiums are now commencing to grow, so care must be taken in watering; do not allow them to get dry. Lælia anceps that have failed to flower will now be throwing out new roots, and these may be rebasketed; indeed, the sooner the better, so as to enable the new roots to have full benefit of the fresh material. Square baskets are required for this purpose, and the best orchid peat obtainable, taking care not to injure the roots, and also to place the growing points as near the middle of the basket as possible, not using more compost than is absolutely necessary, otherwise it will become sour before the season is finished. Cypripedium bellatulum, C. Godefroyæ, C. niveum, and all this section must not be watered oftener than once a week under any circumstances if they are to be grown successfully.

The weather is still unsettled, so great precaution must be taken as to firing and giving air; still attend to sponging and keep pests well down, and thus obtain a clean start for the year. A damping among the plants each morning, and on the floors in the afternoon, but discretion must be used in all these small but important requirements. Temperatures: Phalænopsis house, 65 degrees by night and 70 degrees by day; cattleya house, 58 degrees by night and 63 degrees by day; Lælia anceps, 55 degrees by night and 60 degrees by day; allowing all these to rise or fall slightly, according to the weather.—THOMAS STAFFORD, *Tyntesfield Gardens.*

GREENHOUSE AND CONSERVATORY.

EACH week brings us nearer to the busy season when the striking o. cuttings and sowing seed of different plants will require almost daily attention. To meet the strain of work during March and April, attention should be paid at once to soils of different kinds, placing them under cover, and mixing them ready for use. For sowing small seeds, a mixture of loam, leaf-mould, and silver sand may be made ready now, and stored where it can be kept uniformly moist, but not wet. By mixing these together, and then passing them through a half-inch sieve, the bulk will be available for use at any time. The rough portion should be saved for placing over the drainage. The same compost is also suitable for striking most cuttings in if more sand is added. Suitable sized pots and pans may be washed and crocked ready for use. It is a great gain to devote a small well-heated pit or forcing house to propagation for a month or so at this season, but where there is not this convenience or a melon or cucumber house, hot beds must be resorted to, and the fermenting material should be collected at once, so that it can be turned over several times before it is finally made up. Leaves, especially those from oak or beech trees, are most suitable for the purpose, as they are not so fiery as manure alone and retain an even temperature over a long period. One load of stable manure to two or three of leaves makes a good mixture, and, of course, the greater the bulk the longer will it continue to afford warmth. By making up such beds now, it allows time for the rankest of the heat and steam to pass off. In the meantime, stove plants which have to furnish the cuttings should be examined and thoroughly cleansed before new growth is formed, so that a good start with clean cuttings is made, without which it will be difficult to raise a healthy batch of plants. Fuchsias which have been stored away since autumn will have shed their foliage, and the wood should be quite firm and hard. These make fine objects either in the greenhouse or flower garden when well grown, and if the stock has to be increased an early start should be made to induce the old plants to break. The unripened tips should be cut back to firm wood, and the loose surface soil removed. Lay the plants on their sides and syringe them thoroughly to dislodge any insect pest that may be lurking about them, and then arrange the plants near the glass, where they can have a temperature of about 60 degrees. No water will be required at the roots for a week or so, the buds being induced to burst by spraying the plants over occasionally with tepid water. Other plants which have been at rest may be started in the same way if the stock has to be increased by means of cuttings. Soft-wooded plants, such as iresine, coleus, and the like, should be encouraged to grow before the tops are taken off, as the new growth will strike freely.

The store of tuberous-rooted begonias should also be examined, and if any bulbs are found that have commenced to grow it would be better to put them into small pots filled with sandy soil, and stand them on a shelf in gentle warmth. The bulk of the roots, however, should be kept dormant for another month or so. A good batch of these are very ornamental in the conservatory, especially some of the drooping varieties when grown in hanging baskets. Additional plants may be raised from seed annually, and if grown in a warm border outside the first season the best colours may be selected. Seeds should be sown at once to enable the plants to flower towards autumn. Fill a shallow pan with sandy soil, and make a level surface for the seed, which is very fine. Cover the pan with a piece of glass, and stand in a moist place where the sun cannot act upon it. Keep the soil moist at all times, as the least drought proves fatal after the seeds begin to germinate. Cannas, too, have become very popular of late, and rightly so, as few plants are more beautiful or easily managed. The seed being very hard it is a good plan to steep it for twenty-four hours before sowing. Give plenty of water, and plunge the pots containing the seed into bottom heat of 80 degrees. Do not allow last year's roots to commence growth in a dark cellar or shed, where they have been stored through the winter, but pot them up and remove into a light warm house when it is seen growth has commenced. Unless large plants are required the roots may be divided and potted into small pots, giving them larger ones later on.—R. PARKER, *Goodwood Gardens.*

THE FLOWER GARDEN.

THE remarkably open weather throughout the winter up to the time of writing, excepting a few days towards the end of December, has been eminently favourable for all out-door operations, and where much planting of trees, shrubs, and roses had to be accomplished, there has been little in the way of frost or wet to hinder the work going forward rapidly. It is advisable to finish off the planting of all deciduous subjects within the next few weeks, while those of an evergreen nature, as rhododendrons, hollies, and others of this class may, if the planting be effected in a proper manner, be carried on successfully up to and including the month of April. In the planting of new or improving old shrubbery borders the early flowering species of shrubs should not be overlooked, as these often provide useful material for indoor decoration, and are a decided attraction in the borders in the early spring months. Among the earliest of the shrubs to flower are the Japanese witch-hazels, Hamamelis japonica and H. arborea, which were in bloom outside early in the present month. The leaf-colouring in autumn of these shrubs is also effective. In sheltered situations the shrubby magnolias may be planted, the white-flowered M. conspicua being one of the best and earliest. Others are M. purpurea, M. p. Lennei, M. Soulangeana, all of moderately strong growth, while M. stellata is a smaller white-flowered species of lesser growth. A more often planted early-flowering subject is the almond in its several kinds, while forms of Amygdalus persica flore-pleno, or double-flowering peach, in crimson, rose, and lighter colours are highly ornamental as standards in the shrubbery. Among the prunus P. Pissardi is a desirable form to plant, as, in addition to its early flowers, the foliage which follows is of a rich dark purple red colour throughout the season, and forms a striking contrast to other shrubs. The syringas, better known as lilacs, flowering later, are general favourites, and during recent years these have received attention, and several novelties, chiefly of continental origin, have been added, some of which are worth planting where only the older varieties obtain a place. The double-flowered forms are also distinct; good ones are Madame Lemoine and Virginal, double white; and Leon Simon, double pink. In single flowered, a dark purple acquisition is Souvenir de L. Spath, and Marie Legraye is a very pure white.

Many other flowering subjects may be mentioned as desirable for general planting, the shrubby spiræas for example should not be omitted. S. ariæfolia, flowering in June, is one of the handsomest of the species, the long sprays of white pendulous blossoms being very effective when associated with other shrubs, or equally so when used to form a specimen bush on the lawn. S. Douglasi, producing in July and August flowers of a bright rose pink colour, is also worth planting, as also is the newer S. Anthony Waterer. The Philadelphus, commonly known as syringas, are valuable and highly scented flowering shrubs. P. grandiflorus, with large, pure white flowers, is a handsome variety, although not so strongly scented as is the older P. coronarius or Mock Orange. Standard hawthorns (Cratægus), also in many rich colours of both single and double flowers are now obtainable, and the common single white in large standards is very effective. Among others may be mentioned Pyrus malus, and the John Downie crab; Brooms in variety, Calycanthus floridus, Cercis siliquastrum (the Judas tree), Catalpa bignonioides, Cerasus padus (bird cherry), Halesia tetraptera, laburnums, Viburnum opulus or guelder rose, Ribes sanguineum, and the late summer flowering hibiscus with single or double vari-coloured flowers. One essential necessary to the successful planting of trees and shrubs at this season, is that a good mulching of half-rotten manure or leaf soil be applied after planting, which prevents the evaporation of moisture from the soil, and also keeps the roots in an equable temperature in the event of frosts occurring.

Tuberous begonia seeds should be sown forthwith, if it is desired to raise plants to use in bedding arrangements this season. Pans or small boxes are best for the purpose, and after placing in the bottom a sufficient quantity of drainage, covered with a little rough leaf mould or moss, fill up with a finely sifted mixture of loam, leaf soil, and sand, in equal quantities. To destroy small worms, which are often troublesome, subject the soil previously to fire-heat, or water the pans, after already prepared, with boiling water, and allow it to stand five or six hours before sowing the seeds. These latter should be scattered evenly over the surface; cover the pan with a piece of slate or papered glass, and stand in a forcing house where there is plenty of heat and moisture.—C. HERRIN, *Dropmore Gardens.*

HARDY FRUITS.

PLANTING will still occupy the cultivator's time, especially where new soil has to be prepared or alterations of any kind may have delayed the work; but in some soils planting at this season, and up to the end of February, has its advantages, as the land may be in better condition, if wet or clayey, and the weather remains open. We see how well nursery stock does when planted in March, but it must be borne in mind the trees are small, the roots are not exposed to drying winds, and they receive ample attention during growth, In light soils similar to our own, I prefer to do the planting as early in autumn as possible; indeed, we lift our peach and nectarine trees while the leaves still remain, and they suffer less from drought the next season. Many trees would be benefited by being lifted at this season, in preference to being left barren year after year. I am aware September and October are the best months for root-pruning. Circumstances may have prevented this, so my advice is to lift now the weather is favourable, and with young trees, notably plums, apples, and pears, lifting is a necessity, and will in time save the excessive pruning so often practised. Many of the best kinds of apples and pears have pendulous growth, and if such are hard pruned the crop is poor; yet one often sees these same varieties growing in orchards and bearing freely. Of course, in lifting young trees at this season the work must be done carefully, preserving the fibrous roots. I have recently lifted some plums planted years ago, which should have received attention ere this; but it is better to do the work now than lose a year and a crop also. In planting new trees or re-planting older ones, by all means avoid giving animal manure, or in a short the roots will lay hold of this food and gross, barren wood will result, which in the case of plums and cherries gums badly, and in the end cankers. For heavy soils, such aids as old mortar and road-scrapings from limestone-dressings will be better than manures, while on light land there may be heavier materials to mix with the soil.

At this season it is an easy matter to replace wall trees where they are unsightly examples; and one may often plant a small tree, where space permits, that will in a year or two take the place of older trees of little value. For some years I have followed out a system of purchasing a few trees as reserves, and by so doing one can give newer varieties a trial. In common with most growers, I bewail the lack of good keeping pears; there are few after this date, as in the south I find pears keep badly, and the seasons are much shorter than usually stated; but our friends in the north may be better off in this respect. On many walls between other trees one may with advantage fill in with cordons, for instance, on a south and west aspect. Pears of cordon growth do grandly, and give a few fine fruits; indeed, it may be well to give cordon trees a trial, where large fruits are needed; but let me add, to be profitable these trees must have favourable positions, and be worked on a suitable stock—some do much better on one stock than another. On east and north walls cherries do well, and the cherry grown in a better position well repays for space occupied. For years we had a difficulty in keeping our dessert cherries clear of black fly, but now by winter dressings we have better results. Wall trees, when free of leafage, can be so well attended to that it is best to cleanse them annually after pruning, and previous to renailing. For a winter dressing I find soluble petroleum one of the best insecticides, and in mild cases quassia extract is very good, and this used freely at this date will not injure the buds. All arrears of pruning should be pressed forward, as the trees are earlier than usual owing to the mild weather. Those left to the last, such as the peaches and nectarines, may now be pruned, but defer renailing or tying to the latest possible moment. I am aware many prune and nail-in at the same time, but where summer pruning is carried out there is but little pruning in winter. Peach trees having scale on the older wood should be cleansed as advised above; many paint the older branches also, but with thorough cleansing there will be less need. Trees of the Royal George type which had mildew last year, would be benefited by a dressing of a sulphur solution, adding a wineglass of soluble petroleum to a gallon of mixture.—G. WYTHES.

HIMALAYAN RHODODENDRONS.

AT the opening meeting of the spring session of the Devon and Exeter Gardeners' Association held at the Guildhall, Exeter, a paper by Mr. R. Gill, of Penryn, Cornwall, on Himalayan Rhododendrons was read.

Mr. Gill stated at the commencement of his paper that the culture of rhododendrons in Great Britain had birth concurrently with the publication of Sir J. L. Hooker's journals. Dealing with his travels in Sikkim, the writer mentioned that prior to that rhododendrons were the exception, rather than the rule, in our conservatories, and few persons seemed to have thought that these beautiful plants were adapted to outdoor culture. The introduction of many of the tenderer forms of rhododendrons instituted a new era in outdoor cultivation, and after a few seasons not only were most parks and gardens stocked with these plants, but the manner in which they showed the mildness of our winters led the owners to carry the experiment to still more astonishing issues. By the side of the forests of rhododendrons might be seen sub-tropical plants, which the gardeners of fifty years ago regarded as the aristocracy of the stove house. It was, therefore, only in the southern counties of England and Wales that sub-tropical plants could be grown in a satisfactory manner. The meteorological observations went to prove that the two westernmost counties of England had a climate in many respects superior to that enjoyed by the Riviera, and plants which had been known to be killed off in severe winters in the South of France passed through our own almost unscathed. Whether regarded from the standpoint of landscape gardening, valued for the length of their blooming season, or considered for the beauty of form or variety of colour, they more than repaid the time and money given them. It was true that some of the earlier blooms were liable to be destroyed by the sharp frosts which were prevalent during the early spring, but the display which followed later was a sufficient recompense for the labour. In the West of England and South Wales, in addition to the mildness of the climate, the humidity of the atmosphere greatly favoured the rhododendron.

Rhododendrons were, Mr. Gill observed, great lovers of peat in some form or other. Granite sand, in the proportion of one-third, might be added with good results. The plants did not like a lime or chalky soil, or a stiff water logged clay. Being surface-rooting plants, they would not stand prolonged droughts, but care must be taken to prevent the accumulation of stagnant water round the roots. The lowest branches of the rhododendron should be carefully preserved and encouraged, as they kept the soil around the roots comparatively moist in the driest season. As to propagation, he preferred raising plants from the seed, although it required patience. The paper next dealt with the mode of planting out, and then came some notes of the more important of the forty-three species of Himalayan rhododendrons described by Sir J. D. Hooker. Mr. J. Abrams, gardener to Mr. T. Kekewich, J.P., Peamore, occupied the chair. A most profitable discussion followed the reading of the paper upon the subject of grafting rhododendrons, and it was contended that, to grow rhododendons successfully in Devon, a prepared soil, in which a considerable proportion of peat exists, is absolutely necessary.

OBITUARY.

MR. FREDERICK ENOS WILLEY, who has been curator of the Botanic Station at Sierra Leone, West Africa, for some time past, died, we regret to hear, last week. The news was received at Kew on the 22nd inst., so that full particulars are not yet to hand. The untimely decease of such a promising young man adds one more to the already long list of those who have gone from Kew to develop the vegetable resources of our West African colonies—or to teach and help others to do so—and have died in the fulfilment of their duty. Mr. Willey entered service at Kew in 1892, and a year later he volunteered, with others, for the West African service, and was selected to take charge of the Botanic Station at Aburi during the temporary absence of the late Mr. W. Crowther. He left for Aburi in April, 1893, and returned to Kew after Mr. Crowther had completed his year's leave of absence. In October, 1895, Mr. Willey was appointed to the charge of the newly-founded station at Sierra Leone, and, during the two years of his service, acquitted himself to the complete satisfaction of the governors and all concerned. A wide circle of Old Kewites will deplore the loss of an old comrade, but his memory will long be kept green.

PROFESSOR ERNST L. TASCHENBERG, a celebrated Prussian entomologist, died a few days ago. He was born in 1818. He will probably be best known for his popular treatises upon insects injurious to plants and farm stock.

EXHIBITIONS AND MEETINGS.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE proceedings in connection with the annual meeting and election of pensioners on to the funds of this charity were brought to a conclusion on January 20 by a dinner at Simpson's, 101, Strand, when a few less than a hundred friends and subscribers sat down under the presidency of Mr. Arthur W. Sutton, who was supported by Messrs. Harry J. Veitch, N. N. Sherwood, Weeks, H. B. May, J. H. Veitch, L. Sutton, P. Kay, P. Crowley, H. Williams, de Graaff, A. Barron, Owen Thomas, G. Bunyard, G. Wythes, A. Outram, Glendenning, and others. The loyal toasts were given at the conclusion of the dinner, and duly honoured.

The toast of the evening, "Continued Success to the Gardeners' Royal Benevolent Institution," was proposed by the Chairman amid loud applause; he stated that it was only for about a year that he had a deep interest in the affairs of the institution, for previously he had been but a subscriber, whereas now he had a seat on the committee, and was able to say that all the affairs were conducted in a most efficient manner. To him it appeared that the keystone of the great success of the charity was the treasurer and chairman of committee—Mr. Harry J. Veitch—who, in addition to his official duties, was never tired of working on behalf of the institution. There was great enthusiasm at the committee meetings, yet everything was most carefully discussed and examined. From its foundation in 1851 the Chairman briefly reviewed the history of the charity, referring especially to the patronage of the Queen, the late Prince Consort, and the Prince of Wales, and to the fact that both the Duke of Connaught and the Duke of Teck had presided at the annual festivals of the institution. At the first election of pensioners the highest number of votes polled was 480, whereas that day one candidate obtained 4,249. In those early days there were thirty-five pensioners, costing the charity £512, while the annual subscriptions were £748; this he contrasted with the 1897 record of one hundred and sixty-eight pensioners, costing over £3,000, and the handsome receipt total of £8,575, including the Victorian Era Fund. Mr. Sutton's brief review roused the enthusiasm of the gathering, for such a contrast as these figures afforded proved in an admirable manner the wonderful progress made by the charity, and the growing interest being taken in it. The Chairman referred to the Victorian Era Fund, and the handsome manner in which the Veitch family had helped to make it a success; the interest from this fund would be annually distributed among the unsuccessful candidates. The ability and tact of the secretary, Mr. G. J. Ingram, were eulogised, and it was taken as a matter for great congratulation that the Duke of Portland had promised to preside at the festival. The loss by death of Dr. Hogg was mourned, and Mr. Lees' resignation owing to advancing years was regretted, and the hope expressed that he might be spared for many years yet. In conclusion, Mr. Sutton showed that while they had cause to be thankful for so much success, especially financially, their liabilities were great, and he urged all who interested themselves in the institution to take even fuller advantage of opportunities that might offer for the advancement of the charity than they had previously done. The toast, coupled with the name of Mr. Harry J. Veitch, was enthusiastically received.

Mr. Harry J. Veitch, in response, thanked the chairman for his presence and the assistance he had rendered the charity. He agreed that 1897 was the best year they had had, in spite of the fact that many charities had suffered as a result of the Jubilee festivities. In making a few remarks, he referred to the invested funds, which now amounted to nearly £25,000. This many considered a very large amount, but Mr. Veitch showed that, should subscriptions decline—he did not expect them to do so—the pension could only be continued for ten years. In 1897 twenty candidates had been elected, and the same number that day; forty in two years was a larger number than had been put on the fund in any previous three years, so, if their invested funds were slowly accumulating, so also were their liabilities. He spoke highly of the auxiliary branches, and made special reference to the untiring efforts of Mr. White, of the Worcester branch. The castle he had built in the air some years ago had become tangible; the fund he had hoped to raise for the relief of non-successful candidates had been raised, and, by permission of her Majesty, had been called the Victorian Era Fund, a title suggested by Mr. Ingram. The Diamond Jubilee year had offered an opportunity for making this effort, especially as her Majesty had signified her approval of commemorative funds that had for their object "works of mercy among the sick and the suffering." With reference to the election during the afternoon, Mr. Veitch deplored the loss of 1,035 votes, these being unsigned, and he also expressed a hope that practical gardeners would in future materially assist the charity. He supplemented the remarks made by the chairman anent the relief of unsuccessful candidates by stating that only those who had previously been subscribers, or were widows of subscribers, would be entitled to relief from the Victorian Era Fund, and these would receive sums calculated *pro rata* for the years during which subscriptions had been paid by the candidate or her husband. There was about £130 to divide, and one candidate would receive £10, another £8, another £6 8s., and so on. Mr. Veitch concluded by hoping to see the Victorian Era Fund soon completed, and then, if they still flourished, he had another idea for the furtherance of the cause they were all interested in, and for drawing more money from their pockets.

Mr. G. Bunyard proposed "The Committee" in a few able remarks, alluding especially to the trying work of sorting out the cases of candidates so that none but the most deserving should come up for election. Mr. Owen Thomas responded, and said that though the members worked harmoniously, they were all independent, and carefully scrutinised all bills, cases, &c., that came before them. Eight committee meetings had been held, and there had been an average attendance of sixteen. He spoke highly of the commercial horticulturists who so ably contributed to the funds, and thought that practical gardeners might do much more to help their helpless brethren. In the absence of the Rev. W. Wilks, Mr. H. B. May proposed "Our Country Friends and Supporters," which was duly and ably responded to by Mr. J. H. White, of Worcester. "The Health of the Chairman," proposed by Mr. N. N. Sherwood, was received with cheers and great enthusiasm.

Throughout the evening vocal and instrumental music was ably rendered by the Red Band, kindly provided by the Chairman, Mr. E. J. Monro, Mr. J. N. White, Mr. F. Bevan, and Mr. Mel. B. Spurr of the Egyptian Hall.

SHIRLEY GARDENERS' ASSOCIATION.

A meeting of the above society was held recently at the Parish Room, Shirley, Southampton, the President, W. F. G. Spranger, Esq., conducting the business of the evening. Mr. E. T. Mellor, B.Sc. (London), Lecturer in Biology at the Hartley College, gave a lecture, illustrated by lantern slides, on "Fungi, their Mode of Life and Reproduction." The Lecturer at the outset stated that, like the beggars and thieves of humanity, fungi lived on the labours of others, at least the majority did. A large number of slides showed how they grew, their method of reproduction, and the immense number they were capable of producing under favourable conditions. Even when climatic conditions were most unfavourable resting spores were produced, which could carry on the work when the conditions were become favourable. There will be another lecture on the subject, "Injurious and Beneficial Fungi," on February 21. A hearty vote of thanks to Mr. Mellor brought a very instructive evening to a close.

READING GARDENERS' ASSOCIATION.

At the meeting of this association on Monday last, "Strawberries from Seed, or the Cultivation of the Alpine Strawberry," was the subject of a paper read by Mr. James Hudson, of Gunnersbury, in the British Workman club-room, when Mr. C. B. Stephens presided over a good attendance of members. The subject was certainly a new one, and, perhaps, the first time that a paper on this particular fruit has been given before a gardeners' association. In the discussion which followed, all the members taking part had to plead ignorance of the cultivation of the Alpine strawberry, but after what the lecturer said in its favour, and the fact that a dish of strawberries during September and October would be a great addition to the dessert, as well as being greatly appreciated by employers, many of the gardeners present will no doubt be giving this variety a trial.

Mr. Hudson, in introducing his subject, said: The Alpine strawberry is at the present day a comparative stranger in many gardens, both large and small, but he was fully persuaded that when it is given a fair trial a great majority of gardenerr will be disposed to extend its cultivation. The culture is of the simplest, and given weight for weight upon the same space of ground, the "Alpine" will not be one whit behind that of the average crop of other strawberries. The real success of the culture of the Alpine strawberry is in the raising of one's own seedlings, or in the purchasing of seedlings. The French adopt the plan of growing their stock from seed; but it is only within the last few years that English firms have catalogued the seed, although the plants from runners are, as a rule, offered in most of our strawberry lists in a similar way to the large-fruited varieties. This plan of offering the runners instead of the seed did nothing for, but rather acted against, any extended culture. After dealing fully with the system of cultivation carried out at Gunnersbury, the speaker gave much valuable advice as to soils, and their adaptability for growing Alpine strawberries, also the position most suitable. As to varieties, the Alpine strawberry as it was known only a few years back, must not be taken as the present-day standard of this fruit. The two varieties best for general cultivation are Royal Ameliore and Sutton's Large Red Alpine; the former producing fruits two inches long, whilst the latter, although not quite so large, is equal to it in every other respect, and with some it would be preferred because of its more handsome shape. Other varieties worth growing are Belle de Meaux, colour of the deepest red, and flavour first-rate; Berger Improved, a variety very highly thought of by French growers; and Large White Alpine, which, on account of its colour, makes a pleasing change for the dessert. A hearty vote of thanks was accorded to Mr. Hudson for his interesting paper. A box containing from one hundred and twenty to one hundred and forty spikes of well-grown lily of the valley, many of the spikes having fourteen and fifteen bells each, was shown by Messrs. Rigg and Fixter, The Nurseries, Caversham, and attracted great attention. Eight new members were elected.

LIVERPOOL HORTICULTURAL ASSOCIATION.

The members of this society held their eleventh annual dinner and social evening at the Adelphi Hotel, Lime Street, on Saturday, when one hundred and twenty members sat down to an excellent repast. W. Fletcher Rogers, Esq., presided, and after dinner a full programme of music and song was thoroughly enjoyed, the following artistes giving capital renderings: Messrs. J. W. McDonald, A. L. Howard, G. Smith, A. D. McCormick, and A. G. Davies. The accompanists were Mr. Ernest Hawkins and Mr. Woodward. At the close, votes of thanks were accorded to the chairman and artistes.—J. V. T.

NATIONAL CHRYSANTHEMUM SOCIETY.

A meeting was held on Monday evening last, at Anderton's Hotel, of the General Committee of this society, when Mr. T. W. Sanders occupied the chair. The minutes and correspondence having been disposed of, a list of special prizes offered to the society was read. It was resolved that the Classification Committee shall hold a meeting on Monday next to discuss certain matters relating to the work placed in its charge. The new rules were then submitted and finally approved of for presentation to the members at the annual meeting on February 28. The most important alteration being the appointment of a Finance Committee. A rough financial statement was submitted, and an estimate of the prizes, amounting, with medals, &c., to £757, that will be offered for competition at the society's shows during 1898. New members were elected, and the meeting closed after a somewhat lengthy and formal agenda paper, rather later than usual.

NEW INVENTIONS.

Lawton's Patent Pot-suspender.—A considerable number of contrivances have been introduced for the purpose of facilitating the suspension of pots containing growing plants; but we know of none that are superior to the invention which has been introduced by Mr. J. George, 14, Redgrove Street, Putney, under the above designation. The invention, as will be seen from a glance at fig. 1, consists of a double strand of wire so bent as to form an exceedingly strong spring—so strong, in fact, as to grip an ordinary glass tumbler sufficiently firm to admit of its suspension when filled with water and flowers. In using the suspender the straight portion is thrust down on the inner side of the pot, and the two bent portions are brought over the rim on the outer side as so well seen in fig. 2., and when so placed the pot is very firmly gripped. Two, three, or four suspenders may be fixed to each pot or pan, according to its size, but for a receptacle of moderate dimensions two will be sufficient to hold it securely. The invention will be specially useful in the orchid house; but wherever pots or pans containing plants, or receptacles for cut flowers, have to be suspended, it will be found of much value. We are favourably impressed with the suspender, for it is inexpensive as well as being remarkable for its simplicity and efficiency.

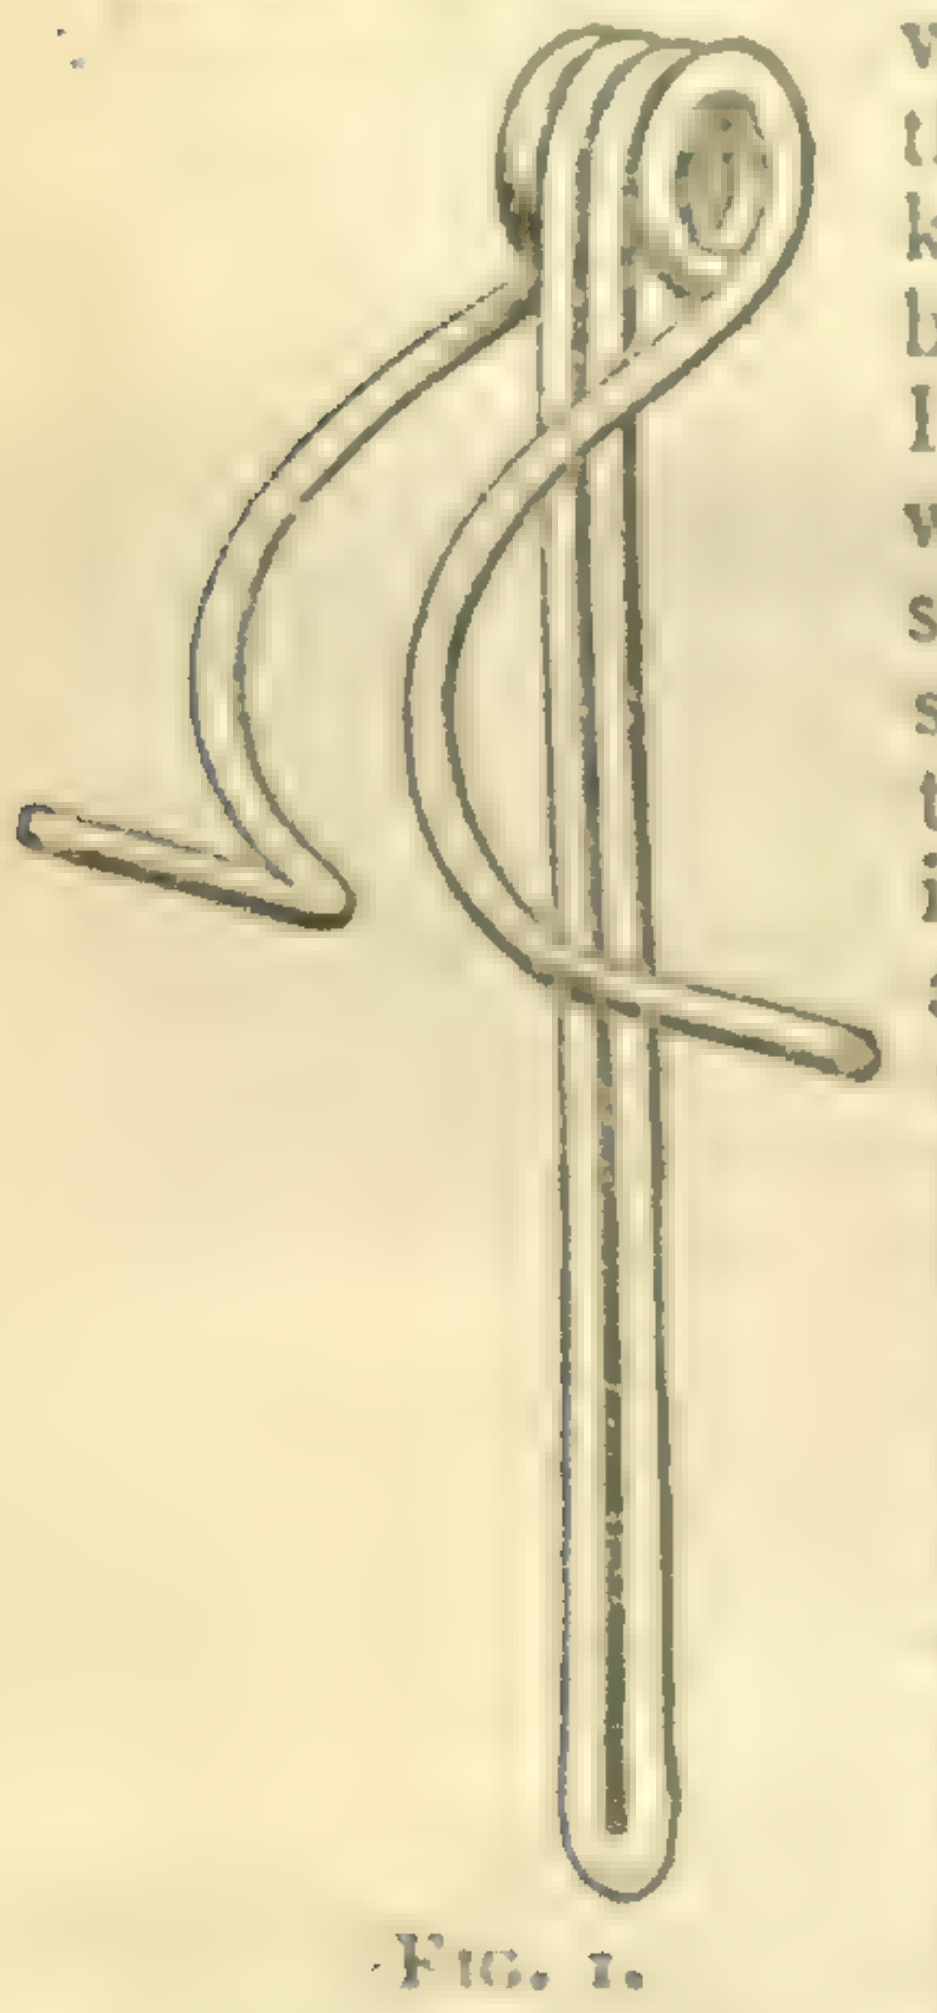

FIG. 1.

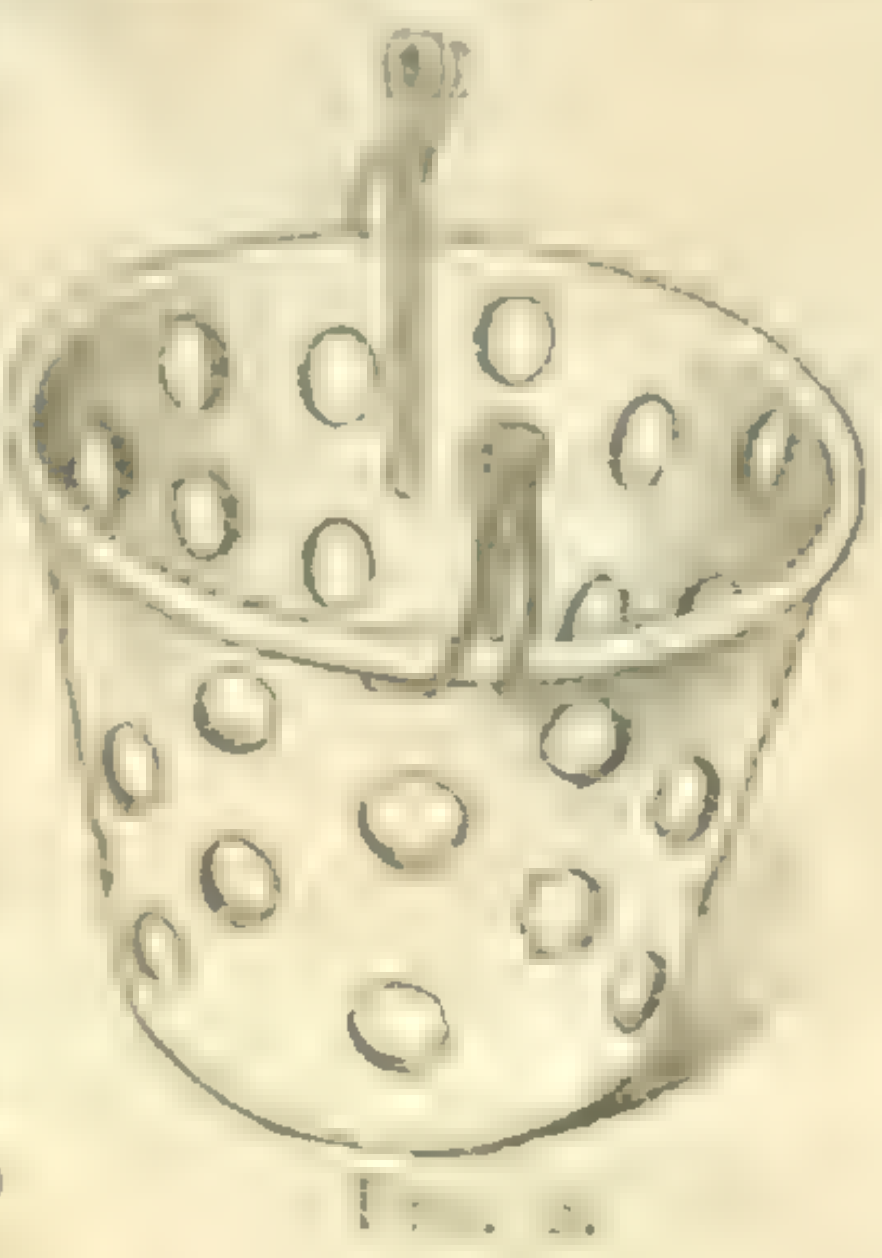

FIG. 2.

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning change of dates

Botany Examination.—C. E. S., York: The work referred "Botany for Beginners," is published at 3s. 6d. by Bradbury, Agnew, and C 9, Bouverie Street, London.

Chrysanthemum Red L. Canning.—G. D., Cardiff: We have heard that anyone has procured the stock of this new market variety, but if you apply to Mr. M. A. Felgate, nurseryman, Henley-on-Thames, who exhibited it November last, you will learn whether he has disposed of the stock or is willing to sell.

Flowers and Insect Attraction.—E. P., Norwich: A series of papers upon the interesting subject of colour in flowers and its attraction for insects has been given by Professor Plateau in the *Bulletin* of l'Academie des Sciences de Belgique. A letter to the secretary of this academy at Brussels will procure the information you need as to dates and prices.

Roses for Archways.—G. R., Hants: Nine good varieties for the purpose you mention are Félicité Perpétue, Dundee Rambler, Alice Gray, Ayrshire Queen, Crimson Rambler, Gloire de Dijon, Madame Bérard, Blairi No. 2, and Waltham Climber No. 1. Some of the Sweet Briar hybrids would also make good roses for archways of considerable extent.

Carbonate of Copper.—J. D., Devon: The following is a good method of producing the ammoniacal carbonate of copper suitable for spraying trees wh in a dormant state. Obtain one ounce of carbonate of copper and dissolve it by means of one volume of 26 per cent. Beaumé ammonia mixed in seven eight volumes of water. This complete mixture may be stored in a co bottle, and when wanted for use should be diluted with nine gallons of wa

Chrysanthemum Bloom.—N. C., Upper Norwood: Your letter containing the small chrysanthemum bloom reached us safely, but it is impossible to name a variety from a flower mutilated by compression between notepaper and envel especially a white flower. We cannot undertake to name florists' flowers, for t so correctly would necessitate the cultivation of complete collections—a matter practical impossibility.

Carnation Gloire de Nancy.—W. D., Southsea: There is no ques as to the hardiness of this variety, sometimes known as the White Clove. In s gardens, of course, the Old Crimson Clove will not succeed first-rate, in such Gloire de Nancy cannot be expected to do itself justice; where one does well there also will the other. The chief objections these carna have is to very light soil over a sandy or gravel subsoil, for here they suffer fr drought in summer and make little growth.

Orchid Cultivation.—H. T., Plymouth: There are several works de to the description and cultivation of orchids, and they vary in price accord their size and comprehensiveness. Either of the following are good works: " Manual of Orchidaceous Plants," by Messrs. J. Veitch and Sons, Chelsea— vols., £5 5s.; "The Orchid Growers' Manual," 25s., Messrs. B. S. William Son, Upper Holloway; and "The Amateur Orchid Cultivators' Guide Book," Blake and Mackenzie, Liverpool.

Malformed Fuchsia Flower.—W. F. S., New Brighton: The sent is one in which there is an attempt at doubling in two ways. There flower within a flower, much after the manner of the Hose in Hose polyan and similar examples, although the inner tube is not much extended; in flowers the tendency to doubling has also proceeded on the usual lines, th the development, or reversion, of the stamens to a petaloid form. In cul plants the tendency to double, in flowers, is often encouraged by superab energy, the result of strong growth and high feeding.

To Destroy a Tree.—G. D., Cardiff: There are plenty of whereby a tree can be destroyed, but they differ considerably in the length necessary to accomplish the end in view. If you do not wish to cut d tree, one of the easiest methods of killing it will be to ring bark it. This may done at once by taking off a strip of bark about a foot wide right round the and near the base; the bark must be removed right up to the wood. Th prevent sap circulation, and you will have the questionable pleasure of tree succumb quickly.

Gas-Lime on Meadows.—A. P., Oxford: Gas-lime will give kill tation and insects with which it comes into contact, for about six weeks af drawn from the gas works, so that to spread it upon meadow land would save for the purpose of killing the grass. Give the meadow a dressing with farmyard manure as soon as possible, or give a dressing with superph using this at the rate of from two to three hundredweight per acre. The phosphates applied now will become available when the grass roots are th vigorous and active; as a manure it encourages the growth of the finer gr clovers. A light dressing of nitrate of soda given at a later period, wh growth has commenced in earnest, will prove beneficial, and if the soil is inclined to soon become dry, then a fairly free dressing of nitrate wi serviceable, and secure a heavy crop of hay. Nitrate of soda, however, encourage the coarser grasses at the expense of the finer ones and th Provided the meadow has been manured, as previously suggested, then the application of nitrate of soda should be at the rate of one to one and a q hundredweight per acre.

Cyclamen Failing.—R. W. D., Croydon: We could find no insects on the cyclamen corm sent, but there has evidently been something at work eating the roots. The grub of some curculio may have been the cause, and might have been imported with the leaf-soil. As the plants are small it would be a good plan to carefully wash the soil from them, cleaning the corms as well as possible, and then repotting in new soil of a light character and using small pots. If the leaf-soil is used, first place it in an oven and subject it to heat sufficient to kill all insect life. Maintain a genial warmth in the house or pit, keep up a fairly moist atmosphere, but give little water to the plants otherwise until they have rooted freely and are making satisfactory growth.

Twin-flowered Cypripediums.—A. B., Epsom: We are obliged to you for your reference and the blooms sent. The form of Cypripedium insigne you have is a first-rate example of the old type; this is, it does not belong to the so-called "montanum" group. Twin-flowered scapes are no doubt due to exceptional vigour in the plants, so that it is very evident your specimens are growing under conditions they fully appreciate. It is seldom, if ever, the case, that a growth giving a twin-flowered scape one year repeats itself the next; the vigour seems to find vent in producing two blooms, and in a succeeding year the plant flowers in the usual way. We have not seen C. Spicerianum produce a twin-flowered scape; your mode of cultivation evidently suits the species. We recently saw three twin-flowered scapes on a specimen of C. Harrisianum.

Maréchal Niel Rose.—R., Surrey: Cut the roses back pretty hard at planting time, so that some strong shoots will be produced from the base and enable you to soon furnish the wall. If there is need of a rod of some length, as in the case of training a rose to the roof, then only prune it back to the point from whence it is desirable to obtain several growths. When the plants are turned out of the pots remove the crocks with the aid of a pointed stick, and also remove any loose surface soil there may be; any roots that can readily be laid or spread out should so be treated, but the work must be accomplished most carefully or much damage will be done. If the roots are not entwined or twisted round and round just inside the pot, then they may be spread out, but otherwise an attempt to spread them will end in breakage and disaster. If the plants are what is known as pot-bound, then loosen the roots slightly, removing crocks and loose soil, then at planting see that the new soil is pressed firmly against the ball so that new roots will be encouraged to penetrate it.

Violets and Pansies.—E. P., Norwich: Thanks for letter. You should keep the violets as cool as possible, for under ordinary circumstances they should flower at the period you wish them to appear. Those in the open ground should be protected during severe weather, such as frost, snow, and driving east winds, by means of a handlight or similar appliance. Give plenty of air on all favourable occasions to those in frames, and do not put them into the greenhouse until about three weeks before you want them. Practically, the same remarks applies to violas, though these will need rather more care to have them nicely in flower for the occasion. Those in pots in frames should have the flower buds picked out, should they appear, until the end of February; give them the warmest and lightest position possible, water carefully, remove all decayed foliage as soon as detected, and take advantage of bright, warm days to give plenty of air. The warmth of a greenhouse should only be afforded two or three weeks before the date given, provided a little stimulation is at that date desirable. We have not the address you need, but will endeavour to obtain it for you.

Names of Plants.—Under this heading we can only undertake to name species and specific varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp moss or leaves as packing material to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that the numbers be legible and firmly attached to the specimens. We cannot promise to name more than six specimens at one time from any one correspondent.

L. B., Liverpool: 1, Selaginella cæsia; 2, S. Kraussiana; 3, S. Mertensi.

B. F. G., Merton: 1, Cupressus Lawsonianus; 2, Eleagnus longipes; 3, Osmanthus illicifolius; 4, Hamamelis arborea; 5, Jasminum nudiflorum.

G. W. Patricroft: Not recognised; send when in flower.

M. M., Chester: Crocus Sieberi; 2, Iris stylosa.

W. T. W., Hull: 1, Euphorbia jacquinæflora; 2, Callicarpa purpurea; 3, Eranthis hyemalis—the winter aconite.

S. L. F., Salisbury: 1, Odontoglossum crispum, a moderate form; 2, Dendrobium primulinum; 3, Lælia albida; 4, Oncidium tigrinum; 5, Cattleya Percivaliana.

B. G. S., Worcester; 1, Eupatorium riparium; 2, Nephrodium molle corymbiferum; 3, Nephrolepis cordata; 4, Asplenium Belangeri.

H. F., Eastbourne: 1, Stachys lanata; 2, Chimonanthus fragrans.

The mean reading of the Barometer during the week at Greenwich was 30·26 inches, and that of the Thermometer 45°·1, the latter being 6°·7 above the week's average in the 50 years 1841—90. The direction of the wind was south-westerly, the horizontal movement of the air being 13 per cent. below the week's average in the 16 years 1860—75. The duration of registered bright sunshine in the week was 3·4 hours. The measured rainfall amounted to 0·12 of an inch.

MARKETS.

Covent Garden.

HIGH prices are being maintained for fruit of the best quality, whether home grown or imported. Bananas and oranges find a ready sale; green vegetables are fairly plentiful, and consequently there is not a big business in roots. Cut flowers are plentiful for the time of year, and prices are moderate.

FRUIT.—English apples, 5s. to 9s. per bushel; American and Nova Scotian, 12s. to 35s. per barrel; English grapes, 1s. 6d. to 2s. 6d. per lb.; Almeria, 12s. to 20s. per barrel; French pears, 4s. to 8s. per crate; bananas, 5s. to 10s. per bunch; lemons, 6s. to 7s. 6d. per box, 8s. to 18s. per case; Canary tomatos, 10d. to 1s. 6d. per tray, 3s. to 4s. 6d. per case; Valencia oranges, 8s. to 15s.; Jaffa, 8s. 6d. to 11s. per box.

FLOWERS.—Arums, 3s. to 5s.; carnations, 1s. to 3s.; chrysanthemums, 1s. to 3s.; eucharis, 3s. to 4s.; gardenias, 3s. to 5s.; Lilium Harrisi, 4s. to 6s.; tea roses, 6d. to 1s.; pink roses, 1s. to 3s.; cattleyas, 6s. to 10s.; Odontoglossum crispum, 1s. 6d. to 4s.; tulips, 6d. to 1s. 3d.; and tuberoses, 6d. to 9d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; chrysanthemums, 6s. to 12s.; marguerites, 2s. to 4s.; mignonette, 2s. to 4s.; pelargoniums (scarlet), 6s. to 12s.; and violets, 1s. 6d. to 2s. per dozen bunches; azaleas, 9d. to 1s. 6d.; stephanotis, 4s. to 6s.; white narciss, 1s. to 2s.; Roman hyacinths, 6d. to 9d.; lily of the valley, 1s. to 2s.: and pelargoniums, 6d. to 1s. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 3s. to 4s. per bunch.

VEGETABLES.—Celery, 6s. to 15s. per dozen rolls; French endive, 1s. 4d. to 1s. 9d.; lettuce, 9d. to 1s.; cucumbers, 4s. to 7s. 6d.; cauliflowers, 1s. to 2s. 6d. per dozen; cabbages and savoys, 3s. 6d. to 5s.; parsley, 1s. 9d. to 2s. 3d.; carrots, 2s. 6d. to 3s.; turnips, 2s. 6d. to 3s. 6d. per dozen bunches; forced rhubarb, 1s. 6d. to 2s.; mushrooms, 6s. to 8s.; eschallots, 2s. per 12 lb.; seakale, 10s. to 15s. per dozen punnets; spinach, 2s. per bushel; Brussels sprouts, 1s. to 1s. 6d. per half sieve.

Borough Potato Market.

Without any quotable change in prices, the potato trade remains quiet. Supplies are still moderate, and nothing but a spell of frost or snow will brighten up the business.

Dunbars, 115s. to 125s.; Hebrons, 90s. to 105s.; Snowdrops, 85s. to 95s.; Bruce, Maincrops, and Sutton's Regents, 85s. to 90s.; Reading Giants and Saxons, 35s. per ton; Belgians, 3s. 9d. to 4s. 3d.; Germans, 4s. to 4s. 6d. per bag.

ENGAGEMENTS FOR THE ENSUING WEEK.

TUESDAY, FEBRUARY 1.—Scottish Horticultural Association.
THURSDAY, FEBRUARY 3.—Meeting of the Linnean Society.

LOVE, COURTSHIP, AND MARRIAGE are naturally subjects of interest for every young girl. The chief ambition is to have a rich husband and an extensive establishment, but her ideas become greatly modified as her experience of the world grows more matured. At last she settles down to the conviction that riches do not mean happiness, and she determines to be content with true worth, even if allied to comparative poverty. When she comes to this frame of mind she makes herself worthy to be a true helpmate to the man of her choice. Her first duty is to obtain the blessing of sound health; Holloway's Pills will give all that is required in this direction if they are taken with regularity.—[ADVT.]

HEATING APPARATUS.

"TITAN" BOILER

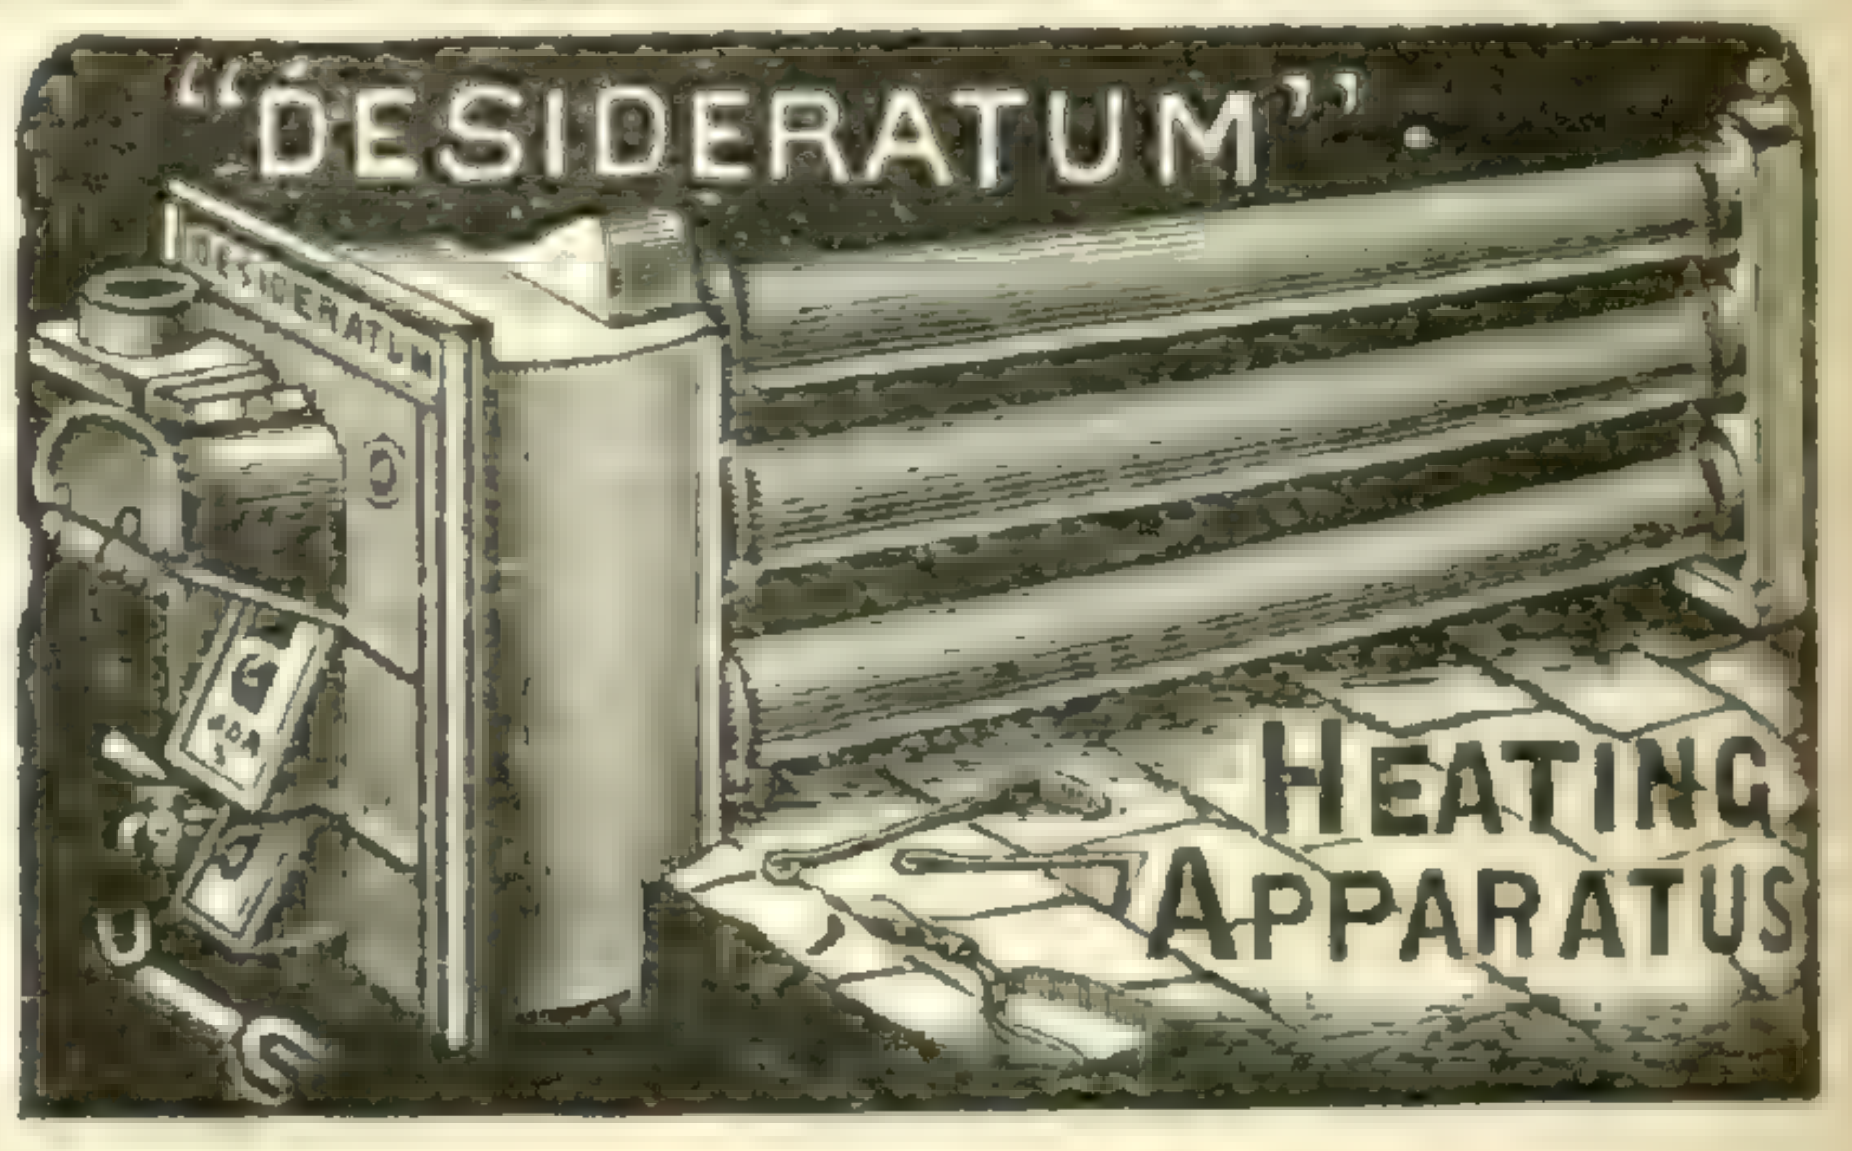
Our "TITAN" Boiler for large ranges of pipes is unequalled. Estimates for complete apparatus.

JONES & ATTWOOD STOURBRIDGE

Our 1896 CATALOGUE contains the largest assortment of Fittings, best selection of Boilers, greatest variety of Radiators, Valves, Gratings, &c., of any in the Trade. 460 pages, Free.

W. Jones' Treatise, "*Heating by Hot Water,*" 220 pages; Cloth, 2s. 10d. post free.

MEDALS AND HIGHEST AWARDS WHEREVER EXHIBITED



Supplied with various arrangements. Special Price List prepared for complete apparatus for Greenhouses 8 feet to 40 feet long. Estimates for larger Houses.

GREEN PEAS—JUNE TO NOVEMBER.

A correspondence was raised in the Daily Press last Autumn upon the shortness of the season when Green Peas are available, both in gardens and on the market. We now offer the following as representing the best collection selected from 1,024 rows we had under trial last season. It would be difficult for us to give precise dates for putting the seed into the ground, as so much depends upon soil and situation. Successional Sowings may be made any time between these dates, and the last sowing not later than the second week in June.

NATIVE GUANO.

BEST AND CHEAPEST MANURE FOR GARDEN USE.

Price **£3 10s.** per ton in bags. Lots under 10 cwt., **4s.** per cwt., 1 cwt. sample bag sent carriage paid to any station in England on receipt of P.O. for **5s.**

Extracts from 22nd annual collection of reports:—

NATIVE GUANO FOR POTATOS, VEGETABLES, &c.

C. H. TINDALL, Bardney: "Used for Potatos. Result very satisfactory; yield much above average. A splendid manure." G. WATTS and SONS, Bournemouth, report: "Good for general purposes. Grand for all Root Crops, Tomatos, and Cucumbers. Find it so cheap; and it does not exhaust the ground like other manures."

NATIVE GUANO FOR FRUIT, ROSES, TOMATOS, &c.

E. F. USHER, Sidcup: "Potatos and carrots, splendid crops; Peaches, Nectarines, &c., splendid. Should not like to be without it on any consideration" G. STONARD, Gardener to Sir A. T. Watson, Bart.: "Used for seven years for Peaches, Grapes, Tomatos, Cucumbers, Roses, and Chrysanthemums with excellent results."

Orders to the **Native Guano Co. (Limited)**, 29, New Bridge Street, Blackfriars, London, where pamphlets of testimonials, &c., may be obtained. Agents Wanted.

IMPORTANT CAUTION.

"**Kola is not a Food. . . Kola is not harmless.**"—*Medical World.*

CADBURY'S Cocoa is entirely free from all admixtures, such as Kola, Malt, Hops, Alkali, &c., and the Public should insist on having the Pure, Genuine Article.

CADBURY'S Cocoa is "A Perfect Food."

EXTRACT from AN OPINION by Dr. ANDREW WILSON, F.R.S.E.

(Combe and Gilchrist Lecturer, &c.), expressed by him in a Lecture on Foods.

"I am distinctly of opinion that the modern tendency to add to Cocoa other substances, mostly of a stimulating nature, is a dietetic mistake, a practice to be thoroughly discouraged. **If you have a pure Cocoa you want nothing else in the way of constituting it a food, for it contains in itself all the principles which go to make up a perfect article of diet.** When people begin to add to Cocoa, Hops and Kola and other things, they are interfering with and altering its dietetic value. Cocoa thus treated is not Cocoa but something else, and I have declined for my part, in all my long advocacy of Cocoa as a food, to recognise that **anything but pure, unadulterated Cocoa can correspond with this definition of a perfect and desirable diet.** I hope the time is not far distant when the public will awaken to a knowledge of the fact that 'doctored' cocoa is not a thing to be recommended or advised as a food"

CADBURY'S COCOA IS ABSOLUTELY PURE, AND A PERFECT FOOD

SUTTON'S STAR PRIMULA (Primula Stellata).

A very distinct race, differing in habit and general appearance from the ordinary Primula sinensis. For general decoration of the greenhouse and conservatory these light and graceful Primulas will become very popular, and as cut flowers the sprays remain in perfection for an unusually long period.

SUTTON'S STAR PRIMULA.

Mr. Alex. McInnes, Falkland Palace, Fife, in the "Gardeners' Chronicle," February 20, 1897, says: "The blossoms being gracefully poised on slender foot-stalks in whorls with stems varying in height from 4 to 12 inches, give the whole plant the appearance of a pyramid, measuring in some cases fully 30 inches in circumference. As a pot plant for general decoration for the greenhouse and conservatory, this light and graceful Primula should become very popular."

Price of seed, white, flaked crimson, per packet, 5s.; mixed colours, per packet, 5s., post free.

SUTTON'S SEEDS, GENUINE ONLY DIRECT FROM SUTTON AND SONS, THE QUEEN'S SEEDSMEN, READING.

UPPER HOLLOWAY, LONDON, N.

THE GARDENERS' MAGAZINE.

SATURDAY, FEBRUARY 5, 1898.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at One Shilling per line, the minimum charge being Five Shillings. Advertisement Office, 148 and 149, Aldersgate Street, London, E.C.

NOTES OF THE WEEK.

MINOR PARKS OF LONDON.

The open spaces within the boundaries of the county of London not exceeding ten acres in extent, number two hundred and eight, and, in the aggregate, occupy an area of three hundred and sixty-six, and their maintenance has become a matter of considerable importance to the public bodies interested. The question as to the manner in which these small spaces should be maintained, and upon what public authorities the responsibilities of their proper keeping should be placed, has for some time engaged the attention of the London County Council. As the result of their deliberation, the Council passed a resolution, a short time since, directing the committee responsible for the parks and other open spaces, to prepare a scheme for the consideration of the Council whereby the whole of the open spaces and churchyards in the county now maintained at the expense of the local authorities shall in future be kept in order and maintained at the cost of the Council, either by its own staff or by making suitable financial arrangements with the local authorities. The reference has been carefully drawn, and we anticipate with considerable interest the report of the committee upon this important question. For reasons that will be obvious to those of our readers who have devoted any considerable share of their attention to the gardens under the charge of the smaller local bodies, we hope that the committee will report in favour of placing the whole of these open spaces under the direct control of the Council. There can be no question as to the benefit that would be derived by the metropolis, as a whole, from all the open spaces being maintained by a central body deriving its funds from the whole of the county. The question as to the advisability of their being maintained and kept up by the Council's staff is equally free from doubt. Notwithstanding this fact, the Metropolitan Public Gardens Association states through their chairman, the Earl of Meath, that they "would be sorry to see the local authorities deprived of control over and interest in them, as would be the case if the London County Council took them over and did the work of maintenance by its own staff." But the Earl of Meath has failed to advance any good reason why the association should regret the smaller open spaces being placed under the charge of men fully qualified to maintain them in a condition that will ensure visitors deriving the fullest enjoyment from them. There may be in the metropolis, as elsewhere, some public bodies that fully appreciate the value of open spaces in relation to the health of the community, and recognise the necessity of employing men with sufficient skill to properly manage them; but speaking in a general way, from long and wide observation, we have not a high opinion of district boards and vestries as garden managers. Were these local authorities differently constituted, and included among their members some who possessed a sufficient knowledge of gardening to enable them to make proper arrangements for keeping the open spaces in order, there would be many cases in which the open spaces could not be satisfactorily managed by them, as the area would not be sufficient to justify the employment of a skilled staff. The London County Council have a strong committee for the control of the parks and open spaces, and they have a staff of superintendents of whom they have good cause to be proud, and it follows, therefore, that they are in a position to keep up these minor parks more efficiently than would the local authorities. In some instances it would be possible to place the smaller areas under the charge of the superintendent of the park in the district; in others they could be grouped, and kept in order by a small staff under the charge of a foreman responsible to the superintendent of one of the parks or the chief officer, as may be considered advisable. When we consider "that in certain cases" local authorities have "refused to take over for maintenance some of the grounds laid out" by the Metropolitan Public Gardens Association, and that in others it has been necessary to place in their hands the spaces "in good order and free of expense," the importance of their management being entrusted to the central body at once becomes apparent.

GARDEN ROSES.

In consequence of the extreme mildness of the weather experienced throughout the winter vegetation is remarkably active in the rosery as in other departments of the garden, and those who purpose making additions or alterations will be well advised in taking the necessary steps to complete them somewhat in advance of the usual date. Notwithstanding the fact that they are in the majority of cases growing freely, roses may still be transplanted with safety provided arrangements are made for replanting them within as short a time as possible of their being lifted, and protecting their roots from atmospheric influences. Planting operations carried out under these conditions will in many instances be beneficial to the plants, inasmuch as the lifting and replanting will so far check the growth as to materially reduce the risk of the tender shoots being injured by the frosts which may be experienced later on. There is yet time for pushing on with the work of planting, and also for considering the classes of roses to plant. To the selection of varieties for the production of exhibition blooms we shall not now refer, as our object is to direct attention to the importance of greater care in selecting roses that are required simply for enhancing the charms of the garden, and yielding an abundance of flowers for use in a cut state. But a few years since roses that produced great masses of indifferently formed flowers, and it may be, with a short season of flowering, were generally regarded as garden roses, and there are still many who consider varieties of this class the most suitable for the garden. This is a misapprehension which cannot be too quickly corrected, for as the result of the activity of raisers of late years, many of the old favourites have been surpassed. There is, indeed, no longer any good reason why the cultivator of roses for garden decoration should have to be content with varieties producing blooms of poor quality, or limiting his enjoyment of their flowers to a short period. The creation of the race of hybrid teas, the improvement in the constitution of the teas, and the multiplication of the chinas, have greatly extended the range for selection, and rendered it possible to fill the beds and borders with varieties that will give a continuous succession of flowers from early in the summer until the autumn is well advanced. Some of the hybrid perpetuals are sufficiently free and continuous in blooming to justify their having a high position amongst garden roses; but there can be no question that the most useful are the hybrid teas, which have accomplished so much in enhancing the interest in rose culture; the hardiest of the teas, which can be depended upon to pass through a severe winter without injury; and the chinas. We therefore strongly recommend the planting more largely of varieties belonging to these three classes than has yet been the case, for with a liberal selection of these three groups there will be an abundant supply of beautiful roses throughout the summer and the greater part of the autumn. To ensure continuity in flowering there must be a vigorous growth, and to obtain this good cultivation is necessary. This for our present purpose may be described as consisting of liberal manuring and deep digging previous to planting, and the generous application of rich top dressings subsequently.

TASTE.

The senses of taste and of smell are so closely allied that it is quite impossible to draw a line between them, the nerves of nose and palate are practically continuous; and though on the one hand many substances of decided flavour are odourless, such as sugar, and on the other, there are subtle scents which only the nose can detect, this is mainly due, in the first place, to the solvent action of the saliva being necessary to disengage the flavour, and in the second to the undeniably greater susceptibility of the olfactory nerves. The human senses, however, are doubtless of limited range in comparison with those of other living beings; and just as we need the telescope and the microscope to extend our range of vision to that of the eagle or the insects, immeasurably excelling the scope of the former, but probably falling far short of that of the latter, so too, there are tastes and odours utterly beyond our ken, as we may know, so far as odours are concerned, by the sudden advent of the rarer moths from great distances to meet their captive mates. In the vegetable world, the variety of flavours is practically infinite, since not merely has the foliage and fruit of every plant its characteristic flavour, sweet or bitter, nice or nasty, subtle or pungent, but this varies not only in the different individuals, but also at different ages of the same; so that the selfsame fruit may be by turns bitter and sour, pleasantly acid, sweet, very sweet, and luscious, and then passing the gamut of human predilections, it runs through all the sickening flavours of taints and ultimate rottenness, though with the medlar, curiously enough, it is only this stage that is really palatable. All this, of course, we know very well, our own particular tastes being in question, but what we are very much in the dark about are the particular tastes and distastes of the lower creation, and especially of that section of it whose tastes run apparently so nearly on the lines of our own that they trespass upon our preserves, and are therefore ranked as foes. Every horticulturist is aware that some plants of precisely the same species are much more liable to be eaten by caterpillar, grub, weevil, or what not, than their fellows; and it is abundantly clear that such plants must emit a pleasant odour, and probably possess an attractive flavour, since repeated clearings simply make room for fresh immigrants to renew the depredations. Other plants, apparently identical, remain unscathed, though actually intermingled with the sufferers. Other factors, of course, may be present in such cases, and doubtless, just as our appetites are whetted or blunted by the apparition of a tender or tough steak, and our teeth are more or less set at defiance by the latter quality, so many of our tiny marauders are tempted or baffled in like fashion by tendernesses or toughnesses beyond our coarser appreciation; which fact lies doubtless at the root of another, viz., that if we have a particular pet plant, of which we take extreme protective care, we are bound, sooner or later, to find a "worm i' the bud," fattening itself up cosily in the precious leafage our coddling has rendered an extra toothsome morsel. Did we know more of these likes and dislikes, tastes and distastes, we might be the better able to protect our plants by masking attractive flavour and odour with repugnant ones; but when we find the omnivorous slug making a hearty meal off the tobacco leaves placed as a deterrent, and flocking in shoals to them and the plant they were intended to protect, with disastrous results, we feel that full knowledge lies still in the womb of the future, and that the old proverb, "there's no accounting for taste," is still as true as ever it was.

FLOWER SHOW ARRANGEMENTS.

A good method for a secretary of a horticultural society to adopt in making arrangements for the annual or other exhibition is to have an index book lettered from A to Z, in which the exhibitor's name, and full address are entered, and the number of classes in which he enters be put in a perpendicular column, in their sequence; next, a class book, in which the classes are set forth in their regular order, a page or half-a-page being allotted to each according to the number of entries expected. As each person enters in a class his name is entered in due order, then a card should be previously printed leaving room for the class to be set forth in writing, and should be written with the name and address of the exhibitor on it in full, one for every entry, the class number being put on the back of each card, and these cards are given to the exhibitors on the morning of the show, and he is expected to place them in their proper order, with the backs of the cards upwards. The judges having made their awards, mark the backs of the cards; an attendant reverses them, places on the front the award in the form of a gummed slip, the award is entered on a card by the judges or by an attendant in the class book, and the work is done. This method necessitates more work on the day or two preceding the show, but when it can be done with greater comfort, and reduces it to a minimum on the show day. All the cards of exhibits to which no prizes have been awarded are also turned upwards by the attendant, and thus every exhibitor has his name and address set forth on his stand, though he may not win a prize. It is difficult to improve upon this simple method. Further, the awards made are set forth in the index book, together with the amount of prize-money won in each class, which also becomes a ledger. As soon as the judging is completed an accurate list of prizes can be compiled from the class book, which proves a great boon to reporters. Under the old system of judging by number, we have known hours consumed in obtaining a reliable list of awards, and not without considerable difficulty, some of the winning exhibitors' cards not being placed on their exhibits until the afternoon was considerably advanced.

Magnolia Campbelli, a splendid Himalayan species, and one that is only hardy in the most favoured parts of the British Isles, such as Devon, Cornwall, and the south of Ireland, has recently flowered in the open air at Messrs. R. Veitch and Son's nursery, Exeter. The specimen has occupied its present position for twelve years, and though it has previously produced buds it has now perfected its large purple flowers for the first time. In the south of Ireland M. Campbelli has flowered out of doors on several occasions. A fine specimen at Kew occupies a position in the Temperate House. A large, freely-flowered specimen would be a fine sight, for the flowers measure from six to ten inches across, and are of a rosy or purple colour outside, shaded with crimson, and white or pale rose on the inner side of the segments. In addition to their fine appearance, the flowers are slightly fragrant. Sir Joseph Hooker, who is so well acquainted with Himalayan plants, says of M. Campbelli that it "forms an immense, but very ugly, black-barked, sparingly branched tree, leafless in winter, and also during the flowering season, when it puts forth from the end of its branches great rose-purple, cup-shaped flowers, whose petals strew the ground." Though ugly when leafless and flowerless, especially in its native forests, Sir Joseph is compelled to state that "Magnolia Campbelli is the most superb species known."

From the Calcutta Botanic Gardens there is being issued a small periodical something after the style of the Kew Bulletin. Botanical, horticultural and agricultural matters will be dealt with, especially in so far as they are connected with the work of the Gardens. The first three issues are devoted to the consideration of a canker that attacks the cacao tree, and this is particularly interesting owing to the correspondence upon the subject which has taken place with the Kew authorities. The cause of the canker and probable remedies are discussed.

Experimental Potato Culture has received a large share of attention the Dalmeny estates, and a considerable success has been achieved. Many the varieties of recent introduction have been grown with a view to determ their usefulness for market, and a series of experiments have been made for purpose of ascertaining the fertilisers best adapted to the requirements of potat The comparative merits of sulphate of ammonia and nitrate of soda were p the test, and the results obtained were decidedly in favour of the amm salts. As in 1896, it was demonstrated that where the land received a liberal dressing of farmyard manure and is consequently in good condition. potash salts, as supplied for example in kainit, are not required. T is as might have been expected, for the soils in the Dalmeny dist are naturally rich in potash; but it in no way affects the advice that usually given for the application of potassic manures to light soils when being prepared for potatos. Some experiments were also made with regard to the of whole and cut sets, and the conclusions derived from them were to the effect that good-sized whole tubers were better than those which had been cut, and that sets of early varieties should on no occasion be cut.

Patriarchial Maple.—Mr. G. H. Beighton writes: "It will probably of interest to your readers to know that there is in Richmond Park a tree of Acer campestre of quite extraordinary dimensions, as it is much larger than any of discovered by the researches of Loudon. The tree is fifteen feet in circumference two feet from the ground, about five feet in diameter, but only some twenty fee of its stature now remain. At its prime, perhaps two hundred years ago, it m have been a magnificent specimen. Each recurring spring it still spreads forth mass of delicate and lovely foliage. It would be of great interest to ascerta any of your readers have cognisance or records of any maple of similar magni Further, it might be of benefit to generations to come if, in the very admirab forestry operations here, a few maples were included in the new plantations. Th tree referred to is the only one of its kind that I have noticed in Richmond P proper, though there are one or two well-grown ones in the neighbourhood.

Teaching Practical Botany.—As we have already informed our read a committee of the London County Council has been considering the practical of laying out plots of ground in certain of the London parks in such a manner will afford assistance to scholars at elementary and secondary schools in the s of practical botany. The committee has reported on the question, and the f ing suggestions have been made: (1) That a very valuable experiment co conducted on a scale sufficiently wide if, in each of three parks, about twenty ro of ground were devoted to the cultivation for school purposes of hardy typic plants belonging to twenty natural orders. (2) The beds should be arranged ne the paths, one bed being devoted to each order. They should differ in size, largest being a little under five hundred feet square, and the smallest about o hundred feet square in area, so that the average of the twenty beds woul approximately one rod. (3) The specimens selected should be such as are in growth, and each should be labelled with its common name and its L systematic name. (4) Labels giving the names and natural orders sh attached to the more important trees, shrubs, and plants throughout the p selected. (5) A botanical guide to the parks selected should be published the superintendence of the Technical Education Board and the Parks Comm (6) Teachers holding printed orders from the Technical Education Board, sh able to obtain from the superintendent in each park such specimens as mig required for botanical study in the schools, so far as they could be supplied w detriment to the specimens. The Parks and Open Spaces Committee, in p these suggestions in the form of recommendations, point out that some f suggestions were considered, but they thought it would be better in the instance to deal with the subject quite in the sense of an experiment; and if, on, it should prove to be resulting advantageously to the schools, possibl arrangements might be extended to the cultivation of important types of the orders of plants, such as fungi, mosses, ferns, &c., and facilities might be a for the study of aquatic plants. The chief officer of the Parks Department re the proposed arrangements as quite practicable at any of the larger parks, but some expenditure would be necessary. Upon that point the chief officer had instructed to submit a report. It is proposed that the experimental beds s formed at Battersea Park, Ravenscourt Park, and Finsbury Park.

The Royal Horticultural Society holds its annual general mee the Lindley Library, 117, Victoria Street, S.W., on Tuesday, February 8, at o'clock. The various committees will meet as usual at twelve o'clock in the Hall to inspect novelties and groups.

Commercial Camphor is chiefly obtained from the oil produced distillation of the leaves, growths, and wood of Cinnamomum camphora, a Jap tree. It is most largely manufactured in the island of Formosa, from wh is sent to Canton for exportation. In addition to this source there are n other plants that yield camphor; indeed, many members of the order L secrete it. For instance, the Bornean Camphor Oil is obtained from Dry aromatica. Quite recently some experiments have been made in New S by Mr. R. T. Baker in connection with Cinnamomum Oliveri, and th were given before the Linnean Society of that colony. The yield was a half per cent., and the product resembled ordinary commercial camphor, a slightly lower melting point.

Magnetism in Fern Life.—In the course of a most interesting upon the Conditions of Life of the Simplest Living Things, Professor Ray L stated that it formerly appeared that the antherozoid cells in fern re moved toward the egg cells (archegonia), which they fertilise, without any reason. But recently a German professor found that the antherozoid c on a glass slide were attracted, as if by a magnet, by malic acid, and investigation showed that the egg cells were coated with a slight this acid.

Early Butterflies.—A correspondent "B. T. I." sends us from Woking three specimens of the Brimstone butterfly (*Goneptyrex rhamni*), accompanied by the following note : "As proof, if any can be needed, of the mildness of the season, I send herewith three full-grown butterflies which I captured this morning on a sunny bank where they were disporting themselves as actively as if the summer had come.

The Royal Society has recently admitted to its fellowship Sir Nathaniel Lindley, Master of the Rolls. Sir N. Lindley is a son of the famous botanist, Dr. J. Lindley, who, in addition to his work in nomenclature, and scientific research, did splendid service for horticulture. Dr. Lindley's "Theory and Practice of Horticulture" is a work that will not soon be forgotten.

Filmy Ferns are ever a source of wonder and delight to those who love ferns as a class, while to the uninitiated they appear as one of the most elegant, delicate, and beautiful of the many families of cryptogams. Those who make a special study of ferns, especially the filmy species, will be glad to hear that Mr. G. S. Jenman has commenced to monograph the Ferns of the British West Indies and Guiana. This is to be published under the superintendence of Mr. J. H. Hart, of the Royal Botanic Gardens, Trinidad, in the Bulletin periodically issued from that establishment. The recent issue, part 5 of vol. iv., deals with the two genera, Hymenophyllum and Trichomanes, twenty-nine species of the former and forty-two of the latter being fully described. Forthcoming issues will be waited for with considerable interest.

Horticultural Club.—The twenty-third anniversary dinner of the Horticultural Club will take place on Tuesday next, when Sir J. D. T. Llewelyn, Bart., M.P., chairman of the club, will preside. Mr. George Bunyard has undertaken to arrange for a selection of vocal and instrumental music. The chair will, as usual, be taken at six o'clock.

Manures for Grasses.—Experiments with manures for grasses were carried out at Dalmeny last year by Mr. Drysdale, agent for the estate. Seventeen plots of one-third acre each were devoted to the experiments. The land was in good condition, having received thirty tons per acre of well-rotted farmyard manure in 1894 and grown a wheat crop in 1895, followed by a barley crop in 1896. The grass seeds were sown in the barley, and the crop was harvested as hay in 1897. The plots were variously dressed with artificials, but certain plots intended to serve as control or check plots received none. The crop on each plot was weighed as hay, and the best result was obtained after a dressing of one hundredweight of superphosphate of lime and two hundredweight of sulphate of ammonia per acre. The profit, after allowing for cost of fertilisers, was £1 15s. per acre over the unmanured plots. The first cutting yielded three tons and the second one and a-quarter tons per acre. A similar experiment, in which nitrate of soda was substituted for sulphate of ammonia as the source of nitrogen, gave a somewhat less favourable financial result. In addition, moreover, the quality of the hay from the sulphate plots was throughout superior to that from the nitrate plots. Hence, it is concluded that for land such as this, in good condition, and situated in the valley of the Forth, sulphate of ammonia and superphosphate form an effective mixture of artificials for promoting the growth of hay.

The Wolverhampton Floral Fete of 1897 resulted in a profit of £421 10s., the gross takings, £2,390 2s. 4d., showing an increase of £87 16s. 9d. on the previous year. At the annual meeting Mr. S. Dickenson referred to the success of the fête during the past nine years, stating that the total profit in that period had been £3,956 18s. 6d., out of which the committee had built shelters, greenhouses, and paid for music in the public parks, and created a reserve fund of no less than £786 12s. Wolverhampton is to be congratulated upon the enterprise and public spirit of its horticulturists and other business men who assist in making the fête so great a success.

Horticultural Conferences at Antwerp, organised by the Royal Horticultural Society of that famous city, are being held at the Palais des Fêtes of the Royal Zoological Society of Antwerp. The first was held on January 30, when Mr. Charles de Bosschere delivered an address upon Exotic Orchids. This is to be followed by a further lecture on the subject on February 6. On February 13 M. J. de Beucker will discuss the merits of various plants suitable for house decoration and general furnishing, and on February 27 will deal with the Management of Villa Gardens. The concluding conference of the present series will deal with Floral Decorations, M. de Bosschere opening the discussion. Exhibits are invited, we are pleased to see, as only by ocular demonstration can such conferences be made of the highest possible value and interest.

Omphalodes verna, a pretty little hardy perennial that is admirably suited for wild gardening, is this year flowering very early. Although a South European plant, it has so long been cultivated in this country that in not a few localities it has escaped from gardens and become naturalised, so that many consider it a native plant. When established it spreads freely, and then, usually from March to May, it produces its pretty deep blue flowers that are so much like those of forget-me-nots, but borne on smaller cymes. Mr. A. W. Kime, of Westhill Gardens, Yarmouth, Isle of Wight, has sent us a few specimens of omphalodes nicely in flower, and picked by him in the woods at Yarmouth on the morning of January 28. Mr. Kime states that the species does not usually flower till April and May in the spot where it is blooming so early this year.

The Burmese Cotton Trade, according to the Customs authorities, is increasing rapidly. The trade is in raw cotton, and during 1896-7 amounted to 57,928 cwt., valued at twelve lakhs of rupees. The recent and continued large demand the raw product in China, coupled with the fine crops of cotton both in Upper and Lower Burma, has been the cause of prosperity. The staple is so good that the Chinese markets will take practically all the first-rate cotton Burma can produce ; poorer qualities find a sale in India. No Burmese cotton came to the United Kingdom last year, but it must be remembered that China took 46,893 cwt. during that period.

Our Coal Supply.—Lord Kelvin, when speaking of the earth's fuel and air supply, once stated that all the known fuel on the earth is the residue of ancient vegetation. One ton of average fuel takes three tons of oxygen to burn it, and therefore its vegetable origin decomposing carbonic acid and water by the power of sunlight, gave three tons of oxygen to our atmosphere. Every square metre of the earth's surface bears ten tons of air, of which two tons are oxygen. The whole surface is one hundred and twenty-four thousand millions of acres, or five hundred and ten million millions of square metres. Hence there is not more than three hundred and forty million millions tons of fuel in the earth, and this is probably the exact amount, because it is probable that all the oxygen of our atmosphere came from primeval vegetation.

Presentations to the Hull Parks.—A short time ago a small collection of orchids was presented to the Pearson Park, Hull, through the good offices of Dr. Hewetson, who, when visiting Brazil, obtained about thirty species, brought home securely packed and cared for, and delivered them at Hull free of charge. Mr. Toyne presented the various parks with about one thousand five hundred tulip and narcissi bulbs.

The National Horticultural Society of France has been honouring several of the leading horticulturists of its country by the presentation of medals of gold, silver-gilt, and silver. Gold medals have been awarded to M. Octave Opoix, head gardener at the Luxembourg ; and to M. Balu, head gardener at the Château of Vaux le Vicomte. Silver-gilt medals were presented to M. Coudray, of the Luxembourg ; and to M. Branchard, head gardener at the Château de Bagatelle, Bois de Boulogne. Silver medals were awarded to M. Pelet, of the Luxembourg ; M. Proust, gardener to M. Berthmont ; M. Huré, gardener to the Princesse de Sagan ; M. Mabillat, gardener to M. Bardac ; M. Bosset, gardener to M. Dessondaix ; M. Quinton, gardener to Madame Carmault ; and to M. Germain Sévres, gardener to M. Guion.

The Field Museum, Chicago, has just acquired by purchase the herbarium of the late Professor Michael S. Bebb, of Rochford, Ill. Professor Bebb was an authority upon the troublesome genus Salix, and his herbarium is probably second only to that at Kew in respect to willows. The entire collection has been purchased for five thousand dollars. It contains over 50,000 specimens, representing 30,000 species, including the valuable material gathered on the Mexican boundary and Canadian Pacific surveys, and the Peary and Greely polar expeditions.

Economic Plants for the United States.—The Secretary of Agriculture for the United States has placed in his estimates for the coming year an item of twenty thousand dollars to be set aside from the fund for the free distribution of seeds, for the purpose of introducing valuable economic plants into the States. If Congress sanctions this item Mr. D. G. Fairchild will be entrusted with the work of introduction.

The late Baron von Mueller.—An influential committee has been formed in Melbourne in connexion with the fund for establishing a permanent memorial of the late Baron von Mueller. It is hoped that the fund will be large enough for the provision of a bust of the late Baron, and also for the endowment of a prize to be associated with his name and awarded as a recognition of botanical, horticultural, or pharmaceutical research in the Australian colonies.

Koda or Kodo Millet in India.—Mr. A. E. Grant, of the Hygiene Laboratory, Medical College, Madras, states, in a letter to *Nature*, that there have been several well ascertained examples of poisoning from diseased or improperly-prepared Koda millet (*Paspalum scrobiculatum*) during the past year in India. Owing to the prevailing scarcity of the usual food-grains, it is probable that Koda millet has been extensively sold and eaten in localities where its use is ordinarily unknown. I hoped, he says, to undertake an investigation myself into this matter, which is one of great importance both from the hygienic and economic points of view. After consultation, however, with Surgeon-Major van Geyzel, chemical examiner to the Government of Madras, I have decided that any investigation worthy of the name would occupy far more time than I have to give to it. I therefore write with a view to eliciting the help of some worker in Britain or elsewhere who has the necessary leisure and facilities for work of this sort. I have samples of the grain, husked and unhusked, from different localities, and can supply the necessary references to the literature of the subject. The investigation, I take it, would have to be of a chemico-biological nature, and would be most appropriate, say, for a thesis, or in connection with some fellowship. I hope that someone who can carry the work right through, and will ascertain the exact source and constitution of the poison (? a volatile alkaloid), will write to me at the address given. In another ten years, perhaps, there will be some attempt to provide the men and the facilities for such work, even in India, when the Victoria Institute is an accomplished fact. We may add that the Kodo millet is an erect grass growing from one to two feet high. In some parts of India it is much grown for food, the grains being used as rice or ground into meal ; they are, however, likely to act as a narcotic poison.

The Prize Cup offered by Mr. H. Deverill, Banbury, to the amateur or cottager gaining the most prizes for vegetables grown from his seeds at the shows in the United Kingdom in 1897, has been awarded to Mr. Alfred Radcliffe, mill warehouseman, 30, Savill-road, Elland, Yorks.

"The Florilegium Haarlemense" for January, 1898, contains fine coloured plates of the following bulbous plants : Hyacinth Hadyn, a single violet variety that has been in cultivation since 1860. Tulips Duchesse de Parma, Thomas Moore, and Ophir d'Or are effectively grouped in one plate ; the former somewhat resembles the well-known Keizerskroon, but has a browner tint of red, while the yellow is less conspicuous ; it has been in commerce since 1837. The third plate consists of representations of three double forms of narcissus, viz., Van Sion, Orange Phœnix, and Sulphur Phœnix ; the former a variety of N. Telamonius, and the two latter both incomparabilis forms.

HARDY WINTER FLOWERS.

THE mild winter—which before these notes are read will probably have been interrupted disagreeably—has produced a record amongst hardy flowers in this garden, which has never in its life been so gay in January. Bees are always abundant at Edge, and are busy as soon as any flowers are open; this year they have been at work all January in every gleam of sunshine, and on some warm days when there was no sun.

To begin with Anemone blanda, some have been in flower ever since Christmas, but at the end of January—the date of these notes—the flowers are in profusion. They are earliest and thickest under a south wall; but as seed is gathered and scattered along the edge of the flower-beds every year, it is gay in many parts of the garden. The colours vary from dark violet to pure white, some being three coloured, shades of light and dark showing in transverse bands. The last are the largest flowers, the variety having been introduced by Mr. Whittall from Asia Minor; but they all grow promiscuously, and it is hard to know whether the seedlings, which flower when two years old, come true. Mixed with these, in choice sunny spots, grow bunches of Hyacinthus ciliatus, better known as H. azureus. These, too, have been in flower all January, and as the seeds are left to come up round the parents, the abundant tiny cones of azure blue make a very effective show. It would not be easy to have too many of them. The winter aconites, which swarm in the shrubberies wherever they are allowed, but do not grow in the grass here, as it is too luxuriant for them, generally begin to show through the soil about New Year's Day. This year they were visible by the middle of December, and were, as usual, the first flowers to attract the bees. Crocus Imperati was not long behind the aconites, several being in flower about Christmas Day. They kept on coming fast till the middle of January, the fine flowering time bringing them all out at once, and making a splendid show. They seem as easily contented as any other crocus, and are planted and sown about in great profusion, but the grass is too coarse here for these too. They are now nearly over, the latest being a variety without any stripes outside the flowers, and very dark purple inside. I have a good many of the white variety, raised from seed collected for me in Italy. These, too, are later than the type, and are less fine and less white than some of the best forms of C. vernus. Crocus Sieberi, also in various shades from white to purple, came in with the New Year, and a fortnight later C. banaticus, a prolific and hardy kind, with rather small and slender flowers of uniform pale purple. The common yellow crocus and several other spring-flowering kinds are out earlier than ever before.

The little Cyclamen coum, with flowers of crimson or pink or white, is now ornamenting a dozen or more choice corners. In some the leaves are plain glossy green, like those of C. Europæum. Others are more or less marbled, and all these varied flowers and leaves seem to come from seedlings of the same plant. I have tried in vain to distinguish between C. coum, C. ibericum, and C. Atkinsi as grown in nurseries, so I make one name do for all. These are not abnormally early this year. It is their habit to begin at Christmas, and neither frost nor snow seem to injure the flowers. To come to snowdrops, their name is now legion, but for plain gardeners like me half-a-dozen names will cover them all. I have no ambition to have snowdrops out in October. By far the best snowdrop I have, which flowers with the old-fashioned type, is Galanthus Imperati; like it, but twice as large. Its constitution is so robust that it is never destroyed by the fatal blight which in this garden attacks such kinds as G. Elwesi and G. Fosteri. We read of several varieties of Imperati. Some have long stalks and some short, but all have large and long flowers. Without speaking disparagingly of any snowdrops, I only say that half the pleasure of them is gone if they are to be overshadowed by labels large enough to contain the long varietal names which we see in catalogues; and I have now learnt the luxury of growing such things without names, so labels are becoming scarce in my garden. The earliest squill is Scilla sibirica, which has come up everywhere capriciously and by ones, to be followed in a month by dense masses in the same places. Are these ones the deepest planted, or individuals of a precocious nature? The earliest daffodil here is always N. minimus. It began this year on January 20, and is now fully out.

Lent roses—Helleborus orientalis and allied species, but here most of them spontaneous hybrids—deserve more than a passing notice. There are hundreds of fine plants which have never been moved since they were first planted as seedlings. The colours of some are charming; delicate pink, almost like apple blossom, or white, spotted inside with purple. Experience has taught where to plant them so as to suffer least from bad weather. Cold winds and snow are their worst enemies; the flowers stand a good deal of still frost without damage. They do best close to the north side of a wall with overhanging trees, or close to a holly or a privet hedge, or under fir trees; they seem to like dark shade; where they see much sun the leaves are generally browned before the beginning of winter, but the leaves of the last year ought to last perfect and green till the flowering is over and the new leaves come. A good dressing of rotten manure in autumn helps the buds to make fine flowers. This year they are exceptionally good and early, all but the very dark purple called H. colchicus being now fully out. Thanks to the sunny May and June of last year the single scarlet Anemone hortensis is now very good both in display of flowers and in colour, and Iris unguicularis, which seldom does anything here but make leaves, has given a succession of flowers all the month.

It should be recorded that many alpine plants are not as early as usual. Hepaticas have hardly shown a bud. The winter saxifrages, S. Burseriana and its hybrids, and S. sancta, S. apiculata, and their allies, which generally are out soon after Christmas, are hardly yet beginning. The delightful little winter varieties of Iberis saxatilis are only just bringing into flower their crowded masses of tiny umbels. As for Morisia hypogæa, which is now flowering out of doors in perfect health, if it proves in the long run as hardy as it has seemed to be in the last two winters, it will make one of the best recent additions to the alpine garden.

Edge Hall.

C. WOLLEY DOD.

EARLY BORDER CHRYSANTHEMUMS.

THE extreme usefulness of this section of chrysanthemums is not nearly so widely appreciated as it should be, and maybe the wonderful enthusiasm created by the large flowering varieties in November has been so absorbing that, to a great majority, the only ones which appear to have any merit are those which are capable of being grown to a large size. There is another reason, and perhaps the most reasonable one, why these early flowering sorts are not much grown, and this is that very few people have any idea of the great variety which has during the last few years been introduced into this section, both from foreign raisers and by our own specialists. A few years ago very few sorts existed which were worth planting outdoors, and most of these needed the protection of a wall to ensure the blossoms opening before severe frosts crippled the plants, but now there are at least one hundred really good varieties which open their flowers in an ordinary border before the end of October.

We set apart a border for these early chrysanthemums during the past year, besides using them in bedding arrangements; for cutting from they were invaluable. The general remark of gardener friends who saw the plants in bloom was one of surprise that such "good things" existed. I had the opportunity also of seeing the extensive collection grown in the open by Mr. Davis, at Framfield, last October, and amongst these I noted several excellent new varieties; two or three of a lovely shade of salmon-pink were particularly attractive, and one called André Falliére, a most charming flower, in form reminding one of the well-known Roseum superbum, but of a beautiful amber colour. It is also evident how valuable such plants will be in gardens with only one or two greenhouses, when in ordinary seasons abundance of flowers may be cut from the open up till the end of October; and if frost is likely to injure the blooms, a covering of some kind may be placed over the plants, or they may be lifted and potted, or placed in a pit, or on the floor of a greenhouse, and have a covering of light soil over the roots, where they will continue to develop their blossoms. It is much best, if possible, to devote a border exclusively to these varieties, where they may be arranged in large groups of each sort and according to the height of the plants; the effect thus obtained is much better than by mixing them in ordinary flower borders, and they are much more interesting together than if dotted about amongst other things. At the same time they may be very effectively employed in association with herbaceous plants, and will add materially to the display during autumn, when most plants are losing their beauty. Clumps of three plants of one variety are most satisfactory when planted in mixed borders. The height of the various sorts ranges from one to four feet, so that very little staking is required by any of them. Though the varieties are quite hardy, it is much best to replant with young stock every spring. This does not involve much labour, and is amply repaid in the superior quality of the growth and flowers. In the autumn after flowering lift one or two stools of each variety and store them in a cold frame to provide cuttings in early spring; these may readily be rooted in pots in the ordinary way, or be planted in a frame like viola cuttings, whence they may be transplanted to the open early in May. It is a bad practice to take cuttings from the open, in winter, before they have made any growth, as these cuttings usually grow spindly and are also very liable to go "blind," but cuttings taken from the frame after some two or three inches of growth has been made, are no trouble to grow.

I have made a selection of varieties from those which have come under my observation, and though there may be very excellent sorts omitted from the following lists, they include none but really good and reliable varieties. The lists are for September, and also for October, but several of the earlier ones commence to bloom in August, and of those for October, some may bloom towards the end of September, so that an unbroken succession of flowers is provided over almost three months. In conjunction with my lists, readers should examine those given in the GARDENERS' MAGAZINE of September 18 and October 16 1897, where the Chiswick trials were reviewed and the heights of varieties given.

September—Alice Butcher, chestnut red, very free; California, yellow, excellent habit in way of Flora; Canari, pale yellow, capital dwarf habit; Deuil du Pére, very dwarf, an improved Little Bob; Early Blush, pale blush, dwarf and early; Feu de Bengale, orange red, first-rate; Frederick Pele, crimson with gold tips; Flora, yellow, very free and good habit; Harvest Home, crimson bronze, very fine; Ivy Stark, golden bronze, lovely flower and habit; Little Bob, crimson brown, very dwarf and free; La Viérge, purest white, sturdy habit; Lily Stevens, white with quilled petals, dwarf and pretty; Madame E. Vaucher, orange bronze, very good; Mdlle. Marie Masse, lilac mauve, large flowers excellent, free and continuous bloomer; Mr. Selly, pale blush pink, charming, very dwarf; M. Gustave Grunerwalde, pale lilac, very free; Nanum, pale flesh pink, early; Piercy's Seedling, orange bronze, a most useful variety; Sam Barlow, salmon pink, tinted gold, pretty; St. Mary, white, very early and continuous; Vice-president Hardy, orange red, most free and effective; White St. Crouts, small flowers very free.

October—Alexander Dufour, bright rosy purple, dwarf; Alice Chausson, warm bronzy amber, fine; André Falliére, beautiful amber colour, first-rate; Charles Gerard, reddish crimson, good; Charles [illegible] deep rose pink, very free; Chev. Auge Baudiere, silky mauve, very free, tall; Comtesse F. de Cariel, most lovely orange bronze, sturdy; [illegible] Queen, very uncommon colour, good; Edith Syart, a capital variety; Harvest Queen, white, excellent habit; Lemon Queen, a deeper shade than name implies; Louis Bettzich, pale rose shaded salmon, very beautiful and distinct, sturdy habit; Madame B. Yung, crimson shaded chestnut, rather tall; Marquis de Montmort, pale mauve, very pretty; Mrs. A. J. Parker, light salmon pink, very charming; Madame Z[illegible] Lionette, yellow suffused with bronze, pretty; Mons. G. Dubor, reddish crimson, capital habit; October Queen, salmon pink, good; O. J. Quintus, rose pink, free and good habit; Prefet Leon Cohn, bright orange shaded chestnut, first-rate; Roi des Precoces, crimson, free and effective.

Trent Park Gardens.

W. H. LEES.

SOME ROSES OF 1895.

CHARLOTTE GILLEMOT, H.T. (Guillot).—We have a few plants of this rose, but looking over the list I see we did not stage a flower of it at any of last year's exhibitions, nor do I remember seeing a bloom on the plants. These, however, are maidens, which throw up long shoots bearing no flowers. It may do better as a cutback. The following is the raiser's description: "Growth vigorous; very floriferous; flowers large, of perfest imbricated form; colour ivory white. This variety is remarkable for its perfectly formed flowers, which are of great beauty. One of the most beautiful roses of this class." I wonder whether we have been cultivating another rose under the name of Charlotte Gillemot, especially as one English grower, after quoting the raiser's description, states, "This has been very free here under glass"; and another rosarian calls it, "Quite first-rate."

HELEN KELLER, H.P. (A. Dickson and Sons).—In striking contrast to the foregoing, this new rose has been most useful to us during the past season, being staged in ten out of fourteen principal classes. The colour is lilac-pink, not a good shade, perhaps, as regards brilliancy, but nevertheless quite distinct. I do not know its pedigree, but it is suggestive of a combination of Mrs. John Laing and François Michelon, producing large handsome flowers, perfect in form, globular, with good depth of petal. Vigorous in growth, very free flowering, the blooms standing erect on remarkably long foot-stalks, a characteristic of the variety. With us it is one of the best, if not the very best, hybrid perpetual that Messrs. A. Dickson and Sons have distributed, and has well deserved the gold medal of the National Rose Society awarded to it at the Crystal Palace in 1895. In habit and wood it closely resembles Mrs. John Laing, and I think will prove nearly as useful. It stood the cold nights of last spring well, scarcely any blooms being deformed or rough, although on all sides of it other varieties were greatly injured.

MARJORIE, H.T. (A. Dickson and Sons).—A pretty little white rose for the garden, of good shape, but too small to be classed as an "exhibition" rose. The texture of its petals is so thin that it damps off at the least wet. Is this one of the reasons why the raiser recommends it "for pot culture," and states that "for forcing purposes this is most valuable"? It is included in Mr. Benjamin R. Cant's list of hybrid teas, and his description of it runs thus: "White, suffused with salmon-pink, flowers full, of medium size, and very pretty, especially good under glass."

MRS. W. J. GRANT, H.T. (A. Dickson and Sons).—This charming rose has had such a very remarkable career, and, in consequence, so much has been written about it that little more need be said. It is well known that Messrs. Dickson, after exhibiting it, and obtaining the gold medal of the N.R.S. for it under the name of Mrs. W. J. Grant, out of compliment to the well-known rosarian of that name, disposed of the entire stock to an American firm, who, having adopted it as their own child, distributed it under the new name of Belle Siebriecht. When, however, it returned to this country, it was quickly recognised and called by the name under which it was first presented to the public. Colour rosy-pink, very free flowering, always in bloom, from first to last, producing clusters of long pointed deep-petalled flowers, which, if required for exhibition, must be well disbudded, although for garden and house decoration the buds may be left. It cannot, with us, as yet be called vigorous or quite hardy, and, in budding, it either does not take very readily, or else the buds are injured by the winter frosts. It appears to have a considerable strain of the tea rose in its constitution, which it more nearly resembles than the hybrid perpetual. No one, I think, has exhibited it so well as the raiser himself, who last year, as in previous years, staged magnificent flowers brought all the way from Ireland; flowers that really seem to thrive upon a sea trip. For my part, probably because we do not manage it well, the flowers have a tendency to develop too quickly after cutting, and therefore have to be discarded upon arriving at the place of exhibition. Nevertheless, as exhibited by the raiser, it is one of the best hybrid teas.

MADAME JOSEPH COMBET, H.T. (Bonnaire).—This is a distinct variety, both in flower and foliage. Each plant sends up four or five long short-jointed thornless shoots, with leathery dark green shiny leaves, and bearing on the top of each shoot a cluster of buds. The bloom is creamy white, of good size, well up to the exhibition standard, but not sufficiently pointed to develop well. It is a late-flowering rose, coming into bloom with us, about the last week in July, or the first week in August. As the hard round buds when opening have a tendency to coarseness, the plant should not be too severely disbudded. The flowers require a hot dry season to open well, and cannot stand the least dampness, for they soon discolour and decay in rain. For this reason I do not think it will ever take a foremost place, and cannot recommend it for a general collection, but only for the sake of variety.

MRS. PIERPOINT MORGAN, T. (H. N. May).—I have included this rose in the list from having seen it so well staged at some of the exhibitions, but we do not grow it. It is a sport from Madame Cusin, and so closely resembles that variety both in form and size that I think it is best described as a bright cerise Madame Cusin.

SYLPH, T. (William Paul and Son).—Not having grown this rose I cannot speak of it from experience. From the excellent blooms of this variety staged last year at various shows it appears to be a useful one, and we have budded a few of it for the coming season, when I hope to be better able to express an opinion. Judging from what I have seen of it in other people's gardens it is a very free bloomer and well adapted for the garden. I cannot do better than give the raiser's description of it when sent out in 1895: "Flowers ivory white, tinted with peach colour; centre creamy pink, a very beautiful blending of colours; large, high centred, and with stiff deep petals; habit erect, a magnificent exhibition rose; the growth is vigorous and the flowers are produced in great abundance, rendering it also one of the most desirable varieties for garden decoration and for cutting purposes.

JOSEPH H. PEMBERTON.

SCARCITY OF LATE WINTER PEARS.

IT often happens that, even in the best seasons, or when there are full crops of fruit, we have a scarcity of good late winter pears. In this part of the country there are very few pears fit for table in March—at least, such is my experience, for I have never been able to keep them good at Syon even as late as that month. Soil and locality will in a measure account for this. I fear, however, that many more growers are in a similar position, as at the last meeting of the Royal Horticultural Society there was but one good dish of pears—Josephine de Malines; yet there was no lack of apples, thus showing a scarcity of good late pears, for on other occasions exhibitors have sent pears with their apples to compete for the flavour prizes. I have come to the conclusion that we are lacking in varieties of really good keeping pears. Certainly the catalogues of leading fruit growers contain a fair list of pears in season from December to April, but so far I have never been able to keep pears so long as stated, and it has not been for want of attention to those small details that assist in preserving fruits. We have left Josephine de Malines, Oliver de Serres, and others hanging on the trees till November, after the leaves had fallen, to endeavour to keep them into the spring; this was an experiment, and it failed.

We have a wealth of good pears which give us supplies from late September to November, but I wish we could have this plentiful supply after Christmas. There are, however, new varieties coming to the front, and we may in time have something akin to Doyenne du Comice among them, which matures in February or later. I had hoped great things from the new Le Lectier, and as regards quality, shape, and size, am not disappointed, for it is a nice fruit; it is a variety raised in France between the popular Williams' Bon Chretien and the French Bergamotte Fortunée, and its season is stated as from January to March. We have it as cordon trees on a south wall; these are young certainly, but gave good fruit, but we could not keep them after December, though it is only fair to add our soil, the warm position and hot summer may have affected its keeping. Still, I fear it is not as late as one could wish, though it will make a good Christmas pear. President Barrabe, a new pear, given an award of merit in December last and a first-class certificate in January, by the Royal Horticultural Society, promises well, and Mr. Allan, of Gunton, is to be congratulated on the way he grew this variety; we have it in cordon form and expect great things, but fear it will ripen earlier than January; it will, however, be a valuable December fruit, and we have room for it, as the quality is excellent. So far, our most useful December pear has been Nouvelle Fulvie, not a handsome fruit by any means, but a splendid quality for dessert at the season named; it does well in our light soil, where it is grown mostly in pyramid form, but it is well deserving of a wall. Josephine de Malines we grow as pyramid trees, but the fruit is none too large, and those who like this variety, will find it worth wall space; when in a distant county I grew this variety on a west wall, where it was really grand. In the north it is worth a warm wall. At Syon we have never been able to keep good fruit of this variety after January. The fruits shown at the meeting alluded to were grown in Berkshire. A revision of dates as to the keeping qualities of pears is needed, as I fear very few dishes of Josephine de Malines could be kept good till April, or even May, as stated in some catalogues.

The best keeping pear we have is Oliver de Serres, but unless this is grown well it is so small that it is not much cared for; it is not a showy fruit, but of fair quality. It shrivels so badly if gathered early that it is then soon unpresentable. If grown on a bush or pyramid it should be well thinned. The useful Beurre Rance, which is so good at the season pears are scarce, does not do well with us. In Gloucestershire we had five dwarf standards of this variety, but could not keep the fruit after January, though in fruit catalogues it is often described as a much later pear. The well-known Easter Beurre is rarely seen at Easter, at least, in a good condition. We cannot keep it after this date, and it is not very productive here I regret to say, though I am aware in many gardens it is a splendid variety. Ne Plus Meuris, a variety often catalogued as a March or later variety, does not keep nearly so late with us, and our large pyramidal trees fruit so freely that unless well thinned it is useless for dessert. Doubtless the stock in our case is at fault, for this pear needs double grafting, while in exposed places it is worth a wall. There are others I could note, but as several of them are earlier to mature than those mentioned there is no need to extend the list. A variety less known—Duchesse de Bordeaux—I saw staged in very fine condition in the middle of February, gaining a first-class certificate. I have not yet fruited it, but it should be valuable for its lateness. It is above medium size, of good shape, russety, and with firm flesh. I hope to get fruits of it this next season, that they will eke out our scanty supply of late pears.

Syon Gardens. G. WYTHES.

Chrysanthemums for December and January.—The following notes may be interesting to those who have to supply cut flowers for indoor decoration, and at the same time keep up a gay display in the conservatory at this dull season. We have now, the middle of January, groups of chrysanthemums all fresh and bright, edged with smaller plants such as primulas, cinerarias, celsias, cyclamen, ferns, &c., the whole presenting a very gay appearance. I will give the names of the varieties as arranged. Phœbus, best yellow to last; Ada Spaulding, delicate blush; H. J. Jones, Cecil Wray, Etoile de Lyon, Boule d'Or, Golden Gem, A. T. Symonds, W. H. Lincoln, Wilfred Marshall, Elmer D. Smith, Lily Gore, refined white; G. C. Schwabe, and L. Canning, the latter is our best late white, either for cutting or for conservatory. We split up the old plants of this latter in April, planting them out on a south border, carefully lifting and potting them up again in September. We grow a big batch of this, as it carries us through February. By growing the above varieties in the ordinary bush fashion (not disbudding), housing late, keeping them in the coolest house available, we secure a grand supply of these ever welcome and useful flowers. I would add that we find the following are superb for cutting from: Ada Spaulding, Wilfred Marshall, Golden Gem, L. Canning, Elmer D. Smith, and Phœbus.—J. MASTERTON, *Weston House Gardens, Shipston-on-Stour.*

HARDY PEACH CULTURE.

I QUITE agree with Mr. Cook (page 51) that an erroneous idea exists regarding the necessity of glass or other copings on walls to obtain successful results in outdoor peach culture. Many failures might be traced to errors in culture. It is but a few years ago since I was asked to look at some peach trees belonging to a gentleman in this neighbourhood which were not satisfactory, although they had been growing there many years. Readers generally will not be surprised when I tell them that the trees were regularly covered and protected every autumn with sheep hurdles and bracken to ward off frost, as though they were tender plants. It is not a difficult matter to sum up half-a-dozen reasons of failure, and, for the benefit of those who may have committed some of them, and have not earned success, I will briefly allude to them.

Perhaps the greatest mistake made is that of neglecting the spread of insect pests early in spring. The one which checks the growth of the tree, and renders it permanent injury, is black fly ; indeed, the whole of the aphis family are troublesome, and often the cause of failure. Black fly is, perhaps, more difficult to eradicate than the ordinary green form ; if allowed to go on unmolested for even a few days after becoming established the leaves curl up, rendering the application of remedies the more difficult. No shoot on a peach or nectarine tree can make progress when hampered with this pest. Syringing the trees with an insecticide of some kind the moment the first fly is seen should be an imperative order. In extreme cases dipping the affected parts in a strong solution of tobacco water is a sure remedy. The same remarks as to cure apply with equal force to the ordinary green aphis. Red spider is an insidious pest, and calculated to weaken the trees if allowed to make progress. It is not in the early days of growth, though, that this insect is troublesome, but generally in August, September, or October, when the weather is warm and the rainfall scanty, for the trees are too often neglected after the crop is gathered. It is then that red spider makes its presence felt all too keenly. If steps are not taken to arrest the spread of this pest the energy of the tree is reduced, and the wood and buds cannot be so perfect as otherwise. All practical cultivators of fruit trees will agree with me that maturation is essential to fruitfulness.

Another source of failure is pruning at the wrong period. Too many trees are not pruned until spring, many just before the buds burst into bloom, and some even after that period. Directly the fruit is gathered is the correct time to prune the trees, according to my notion of the cultural requirements of peaches. Judiciously remove surplus growth at the period named, for when the leaves are upon the trees a better idea is gained of the space to be occupied by future growth than when pruning is deferred until the trees are leafless. Overcrowding the branches is another source of failure to secure the finest specimens. While overcrowding is not absolutely detrimental to a heavy crop of fruit as far as numbers are concerned, it certainly is when high quality is required. What I mean by quality in peaches is large size, rich colour, and what is even of more importance, fine flavour. This latter attribute cannot be obtained when the fruit is deprived of sunlight and air. If this doctrine is accepted as being correct, the merest tyro in fruit culture will readily grasp the advantage gained by judicious early pruning.

Too much manure dug in about the roots is another source of failure. Some argue that a strong, vigorous growth is the best, and to obtain this they stimulate the trees into violent action by the application of rich manure. The result of such injudicious treatment is gross unripened shoots, that are liable to gum, do not set their bloom buds ; indeed, many shoots of this description do not show a profusion of buds, they are much more addicted to the production of lateral growths. Instead of digging-in manure about the roots, it is better to assist the trees when necessary when carrying a heavy crop of fruit by liquid manure and surface dressings of half-decayed manure, and the addition of artificial manure discriminately chosen and properly applied. Too many ignore the value of mulching fruit trees, but there cannot be two opinions as to its value in encouraging surface root action. Mistakes, also, are made in this detail, and the greatest is that of applying the mulching in the autumn and allowing it to remain until it decays, irrespective of the weather. Under such conditions the roots are robbed of the warming influence of the sun during the spring and early summer. Too often the roots of the trees are much too deep to receive any benefit from solar heat, in consequence of deep planting and continued digging afterwards. A firm soil, with the roots as near to the surface as possible, are the conditions that favour success. In my case the soil within a yard of the wall against which the trees are growing has not been disturbed for ten years, and I have no cause to complain of results. It is a very good plan to trench the soil within three or four feet of the wall once in two or three years. This is often the means of checking a too exuberant growth, and at the same time encourages the production of fibrous roots by the severing of those of a fibreless nature.

Swanmore Park Gardens.

E. MOLYNEUX.

The Miniature Trees of China and Japan have ever been a source of wonder and interest to horticulturists, and it has generally been considered that these curious specimens are the result of generations of patient stopping, training, and general dwarfing. A contemporary, however, is assured that the following is the *modus operandi*. Take an orange, cut a hole in the peel the size of a shilling, remove the pulp with a spoon. Fill the skin with a mixture of cocoanut-fibre, moss, and charcoal, chopped fine and stiffened with a little loam. Put in your acorn, or seed, or kernel of any tree you wish to dwarf, then place the orange-peel in a vase or tumbler, after the manner of an egg in a cup, and stand it in a window. Water it occasionally through the hole. In due time the tree will push up its stem and the roots will come through the peel. They must then be cut off flush with the peel, repeating the process at intervals for about two years and a-half, when your tree will assume a stunted, gnarled appearance, like an old tree. When the roots are cut for the last time, the orange-peel, which, strange to say, does not rot, must be painted black or varnished. This shows that the production of dwarf plants is due to a systematic checking of their root growth.

MULBERRIES AND SILK-WORMS IN AUSTRALIA.

FOR many years past the advantages possessed by New South Wales for the successful practice of sericulture have been fully recognised, but so far the industry does not appear to have progressed much beyond its experimental stages. When the notice of the colonists was first directed to the possibilities of sericulture, mistakes were made in obtaining eggs prior to making provision for the subsistence of the worms, and consequent failures dashed the hopes of the inexperienced enthusiasts who so unpreparedly essayed the culture of silk. In some of the other colonies sericulture has been attempted with varying success, and hopes are entertained that cocoons may yet become articles of export, the idea of manufacturing silk locally being impossible, by reason of the absence of the necessary experienced skilled labour and complex appliances of modern weaving machinery. It has been pointed out to Australian farmers that the first practical step towards acclimatising the production of silk is the placing under cultivation to the white mulberry, sufficient land to grow the only food for the worms which makes systematic sericulture possible. The caterpillars, called "silk-worms," will live on the leaves of various kinds of trees, but it is only when they are nourished on the leaf of the white mulberry tree that they will form cocoons of a marketable value, capable of furnishing silk suitable for the looms of the manufacturer. There are several varieties of white mulberry adapted to the demands of the cultivator anxious for immediate results, the young trees of which supply an abundant crop of leaves of good quality, useful during the early life of the silk-worm, though not the best for the completion of the process of silk culture.

If colonial farmers would, in addition to their other crops, cultivate about two acres of white mulberry trees, they could in the third year of growth from seed, begin experimenting in earnest upon the rearing of worms. With a unit of force, comprising a half-grown family of about eighty silk-worms, the appropriate unit of cultivation would represent a plantation of about two acres of white mulberries, bearing some 5,000 trees. After removal and thinning out, the silk farmer should have, in their third year of growth, 2,500 trees, which, if they have thriven, should yield from a pound to two pounds of leaves each, or, altogether, from a ton to two tons. The cultivator is then in possession of enough raw material, in the form of mulberry leaves, to produce from one cwt. to two cwt. of cocoons, which, if of good quality, would be worth £4 or more per cwt. Arrangements for housing silk-worms need not be very elaborate. Walls of wattle-and-dab, smoothed and whitewashed inside, with a roof of thatch, constitute an ideal silk-worm house. Should the producer desire to limit the area under mulberries to two acres, he will find that his annual yield will be a fairly steady crop of from five to seven cwt. of cocoons. According to authorities, the yield of leaf per acre in France and Italy, from well-grown trees on fair land, is estimated at from 7,000 to 8,000 lb.

The first step in sericulture, viz., the formation of white mulberry-tree plantations, is one the results of which have to be waited for ; and this is why so promising an industry has not obtained a better foothold in Australia. Of course, people have endeavoured, and continue in their endeavours, to rear silk-worms without first growing proper food for them ; but every such attempt at silk production has failed, and is, in fact, foredoomed to failure. Recently the attention of the colonists has been more strongly directed to the possibilities of sericulture by the labours of the New South Wales Agricultural Department, some thousands of trees and cuttings having been planted during 1894. At Booral, in the Newcastle district, the Colonial Government has rented a white mulberry plantation, extending over seven acres, with a view of testing the practicability of developing a profitable sericultural industry. On the expiration of the lease at Booral it is intended to continue the experiment at the farm attached to the Hawkesbury Agricultural College, in which locality a large number of white mulberry trees have been planted for future use.

During the year 1894 the New South Wales Parliament voted a special grant of £200 in aid of the Women's Co-operative Silk-growing and Industrial Association ; but it is in the extension of the plantations of white mulberry trees that the colonists must look for the real growth of the sericultural industry. A convincing effort in this direction has been made by the settlers of New Italy, near the Richmond River. These people comprise a number of Italian families, who came out in 1881 [illegible] the Marquis de Ray to settle on the island of New Ireland, in Polynesia, and who, on the failure of their leader's scheme of colonization, [illegible] their way to New South Wales. These immigrants have planted successfully a considerable area with white mulberry trees, and have in[illegible] the industry of silk production in the region of the northern rivers, [illegible] fair prospects of its future profitable development. The silk is sp[illegible] the caterpillars of the genus Phalæna, of which the Phal[illegible] produces the greatest quantity ; but the Phalæna bombyx is [illegible] commonly employed for this purpose in Europe. The best silk-worms are obtained from Japan and Italy, the former being preferred [illegible] procurable. There can be no question that practical sericulturists, possessing the requisite amount of capital, would find in New South Wales an extensive and remunerative field for the exercise of energy [illegible] enterprise.

Sydney.

JOHN PL[illegible]

Birds and Fruit Trees.—At a late meeting of a fruit growers' association near Brisbane there were loud complaints concerning the destruction of [illegible] birds, and that the laws protecting them have been long a dead letter. The chairman said that fruit growers were in danger of being deprived of their best friends, the insectivorous birds—finches especially. The meeting decided that the divisional boards and the Agricultural Department should be written [illegible] urged to do all they could to prevent the trapping and shooting of birds. [illegible] were also expressed that other societies would take up the grievance. [illegible] birds are protected by a law, it is all but unknown, and certainly not in [illegible]

LEAVES FROM A RAMBLER'S NOTEBOOK.

MEN AND METHODS.

THE turn of the year, with spring and its attending work in prospect, brings gardeners face to face with numerous duties, and a decision must be arrived at as to the best ways and means of accomplishing them. In this there seems to be no hard-and-fast rule, for though in every case principles must to some extent be the same, the methods of applying them vary considerably. Nowhere is a gardener so much at home as in his own garden, and interviewed there one has no difficulty in seeing his methods, and also, if successful, of observing the implicit faith he puts in them. In his own sphere the gardener is not loth to argue in favour of his mode of procedure, and sometimes is apt to ridicule any other, no matter how successful, simply because he has learnt to pin his faith on one. To anyone quite uninitiated in the gentle art this conflict of opinions is puzzling, and frequently amateurs in difficulty are at a loss to know how to proceed, because Mr. A says this is the best method and Mr. B recommends another quite different. Both men speak from experience and their words are to be relied upon. How, then, shall the novice proceed? He frequently loses confidence and is slow to accept the advice of either; whereas if he took the trouble to get to the root of the matter he would find that the principle of the thing was the same in both cases, and the two gardeners went different ways to reach the same end.

Garden visiting is always a pleasant occupation to anyone interested in horticulture, and there is no better opportunity of studying men and methods. When two gardeners meet they invariably talk shop, and if the meeting takes place at a show or outside the precincts of the garden, then the conversation is general; but when friend meets friend in the garden which either controls, they come at once to detail, and exchange views over the cultivation of this crop or that. Tenacity of idea is generally a strong point with gardeners, and many men having proved from experience the success of any particular method, are ready to swear by it, and look upon any other as being quite beneath their consideration. Others, again, are borne here and there by every breeze of opinion that blows, never forming one of their own, nor sticking to anyone else's long enough to give it a fair trial. Rarely are such amongst the most successful, and, as is generally the case when making comparisons of this kind, the best plan is to strike a medium between the two; always being on the alert when viewing the operations of others, to take advantage of anything that looks like improvement, but at the same time having confidence enough in our own opinions to avoid following the lead of every would-be reformer who comes along.

Young gardeners during their years of probation, frequently have opportunities of seeing this conflict of opinion that exists among heads, and in some cases it has anything but an inspiring effect. Imagine, for instance, a young man of studious, thoughtful turn of mind who is anxious to make himself competent, serving for a period under a gardener of set and somewhat biassed opinions. He has faith in his chief, who maybe is not slow to impress upon him that his methods, founded on experience, are correct, and any other ways of treating certain crops, or doing specified work, are therefore wrong. The young gardener gets to look at matters in the same way, and frequently finds himself in a quandary of doubt when he leaves the establishment to pursue his fortune in some other under a head gardener who holds different opinions to those of his former chief. This kind of thing has damped the ardour of more than one young man, and been the means of lowering his interest; while making due allowance for differences of opinion, and admitting the right of any man to be justified in working on any methods which he has proved to be successful, he should not go so far as to assert that his way is the only right one, and ridicule every other. Every young gardener may learn a lesson from this by taking observations of varied methods, then when he is in a position to please himself act on the one that appears to him the most practical. Recently I heard of a young man who, when starting at a fresh establishment, was instructed to do a job in a certain way. He protested that Mr. So-and-So, under whom he had previously served, followed a different course. "When you were with Mr. So-and-So," replied the chief, "you worked his way. Now you are with me, you will work my way, and when you are a head gardener yourself you can work your own way." Surely this taught a better lesson than abusing the work of a brother gardener, while it was clear, and to the point.

I did not intend to particularise at all, but current work in hand reminds me forcibly of one of the points "where doctors disagree." I refer to pruning, all arrears of which, as the calendars put it, should be now completed. Here we have a case in point, and the other day an amateur was in a state of perplexity about some young apple trees he had just planted. "Don't prune them at all the first season," said one expert, going on to give his reasons for not doing so, and proving, at any rate to his own satisfaction, the correctness of his theory. Another expert comes along, this time a firm believer in first-year pruning. He, of course, ridicules the advice of the former as being against his principles, and attempts to illustrate the advisability of pruning after planting by showing subsequent weakly growths breaking from the tips of unpruned shoots, with all the lower buds blind. He tells the puzzled amateur that non-pruning the first season is conducive to waste of wood, and opposed to the principles by which sturdy, well-shaped trees are obtained. Between the two the novice is puzzled to know how to proceed, and the moral obtained from it seems to be that in gardening there is a danger of one being overdone with advice. Another grower I know has determined to prove for himself, having planted trees, and pruned some, leaving others unpruned. The result will doubtless satisfy him, and in due time the horticultural world will have another advocate of either one system or the other.

Just one more instance, and this time vegetables—onions. We note the advice of two successful growers and exhibitors. One, whom we will call Mr. A, gives his methods of cultivation, and says the correct thing, after raising the onions in heat, is to carefully transplant them in their permanent quarters with a trowel, disturbing the roots as little as possible, and removing the plants with good balls of earth attached. He goes on to detail the ill effects if this advice is not followed, and it all sounds so feasible and practical that we are disposed to accept it as the correct thing. Then Mr. B steps in, he also being an expert in the art of onion culture. He tells you Mr. A's theory is all nonsense about the planting with good balls of earth. His advice is, when transplanting, to wash away every particle of soil from the roots, and thus give them a clear start in the fresh compost. He argues that the onions make less root-growth, and the force of the plant goes to the feeding and maturing of the bulb. He clinches his argument by the production of first-prize cards for onions, and knowing both men to be successful growers, how can we refute the statements of either? As Sam Weller would put it, "it ain't to be done," and is only one instance in the many of the different ways leading to the same goal. The study of "men and methods" is an interesting one, and, in spite of the complications existing, the summing up seems to be contained in the old adage—Take the advice of both sides and then act for yourself.

H.

CHISWICK AS A SCHOOL GARDEN.

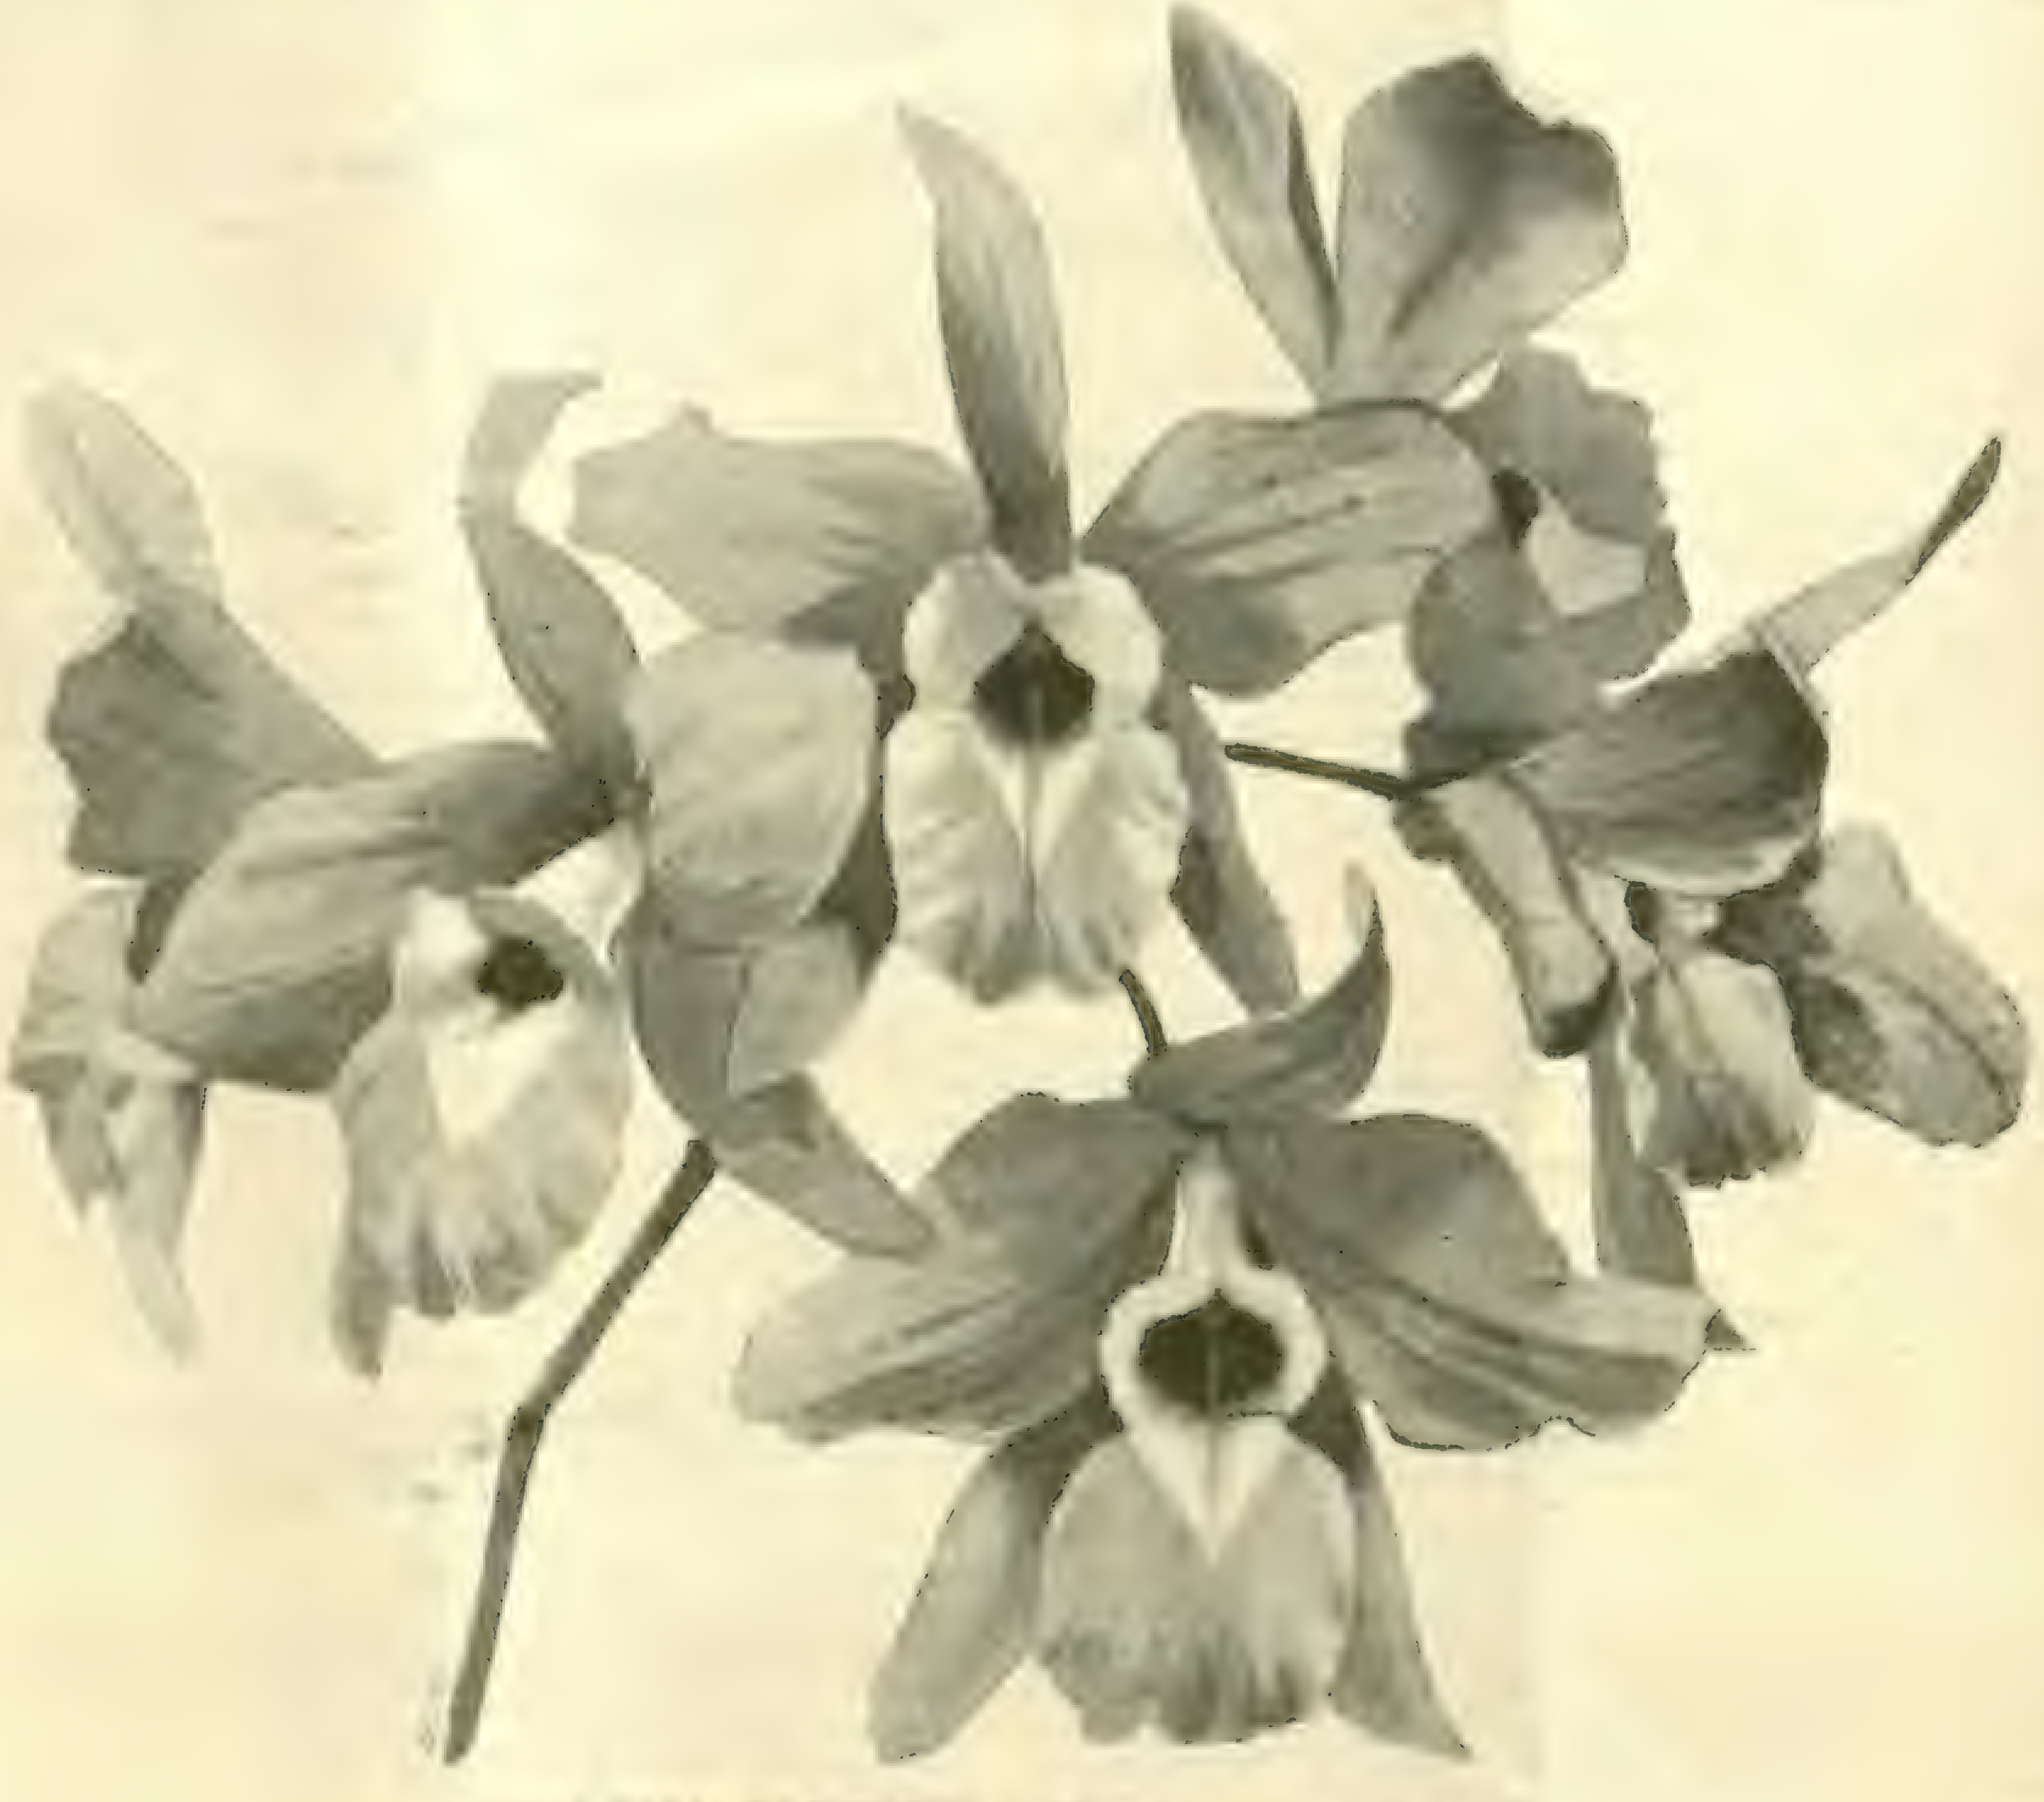
THE mention in a recent issue of the scholarships available at Chiswick in connection with the forthcoming R.H.S. examination again serves to attract attention to the old garden and its uses. Whatever may be the criticisms bestowed from time to time on Chiswick and its management, there remains the undoubted fact that it is practically the only advanced horticultural school garden in the kingdom in which general horticulture can be taught. Of course I do not overlook first-class private nursery and market gardens, all of which enable gardening in a very wide sense to be learned, but none of these occupy the same public, and I may almost say academical, position that Chiswick does. I may be told of a garden in the Regent's Park as being also a public school garden, but whatever its pretensions, it is evident it cannot properly be placed in comparison, or in the same category as a school of practical horticulture, with Chiswick. The former may be able to evidence what is termed decorative gardening; the latter illustrates in admirable fashion fruit culture, inside and out, vegetable trials, and both plant and flower culture, within and out also. Chiswick has one other great advantage as a school. It is presided over by a first-class practical gardener, and to the future gardener such supervision is worth a score of pure scientists or theorists. Of all things the future gardener, whilst yet a learner, needs to be grounded in hard practice, and then, if a persistent learner, theory and science can follow with all the greater ease. Then again, in garden practice, whatsoever may be the temporary and changing value set upon mere decorative gardening, the importance attached to productive gardening as found in fruits and vegetables never varies; indeed it becomes the greater as the years roll on. Hence a professed advanced school garden should give practical instruction in these great cultural elements as well as in decorative gardening

There is attached to Chiswick also, though not essentially under the R.H.S., an exceedingly useful society in the Gardeners' Mutual Improvement Association, this is a society well worth tangible support by the R.H.S. council, as its meetings are held in the old council room. Such a society presents most attractive as well as instructive features, to young men. They are features that hundreds of young gardeners in isolated country places would be only too delighted to be able to utilise, but cannot. It is difficult to overestimate the usefulness of such gatherings as this association furnishes, not only for acquiring knowledge from each other amongst the members, in learning to organise thoughts, and to express them in terse language, but also in bringing gardeners together for social intercourse and interchange of opinions. Altogether, Chiswick seems to enjoy very many advantages, and youths there possess privileges and have opportunities that many other young gardeners do not share in.

There is one matter in relation to these proferred scholarships at Chiswick, that needs full elucidation. As well known the examinations in each year are open to any and all candidates, male and female. Nothing is stated in the scholarship papers, so far as published, that in any way indicates the donor's intentions with regard to sex. It is well known that women do enter the field of labour now as gardeners. Are these eligible for the Chiswick scholarships, or not? It is true the term "he" is used in the conditions, but it is not emphasised, and may be read, as it stands, to include "he" or "she"—at present it is a comprehensive or inclusive term. One point needs to be made very clear. When women are included in the ordinary garden staff at Kew, it is difficult to see how they could consistently be excluded from Chiswick. The matter is not at all to be determined by sex bias and prejudice, but by good sense. When the R.H.S. throws the doors of its examination rooms open to male and female alike, without distinction, and on a footing of absolute equality, can distinctions as to well-won scholarships be consistently created? I fail to see how they can. I hope to learn later that very many more young gardeners have entered for the examination than last year. It is for their benefit chiefly it is instituted. As an examination of cottagers, and similar very elementary amateur gardeners, it is absolutely unfit, indeed absurd; but it is not possible to suppose the promoters ever contemplated the examination would be for these classes. A. DEAN.

LÆLIA RUBESCENS.

MOST orchids that have been in cultivation for any lengthy period have several synonyms, and Lælia rubescens is not an exception. It was first made known by Dr. Lindley, who, in 1840, was shown a specimen that had been purchased from Mr. J. Knight, a member of the firm of Knight and Perry, which preceded Messrs. J. Veitch and Sons, at the Chelsea Nurseries. L. peduncularis, L. acuminata, and Bletia rubescens are names under which the species has been known, for while some consider that different species are referred to under the two former names, yet it is now generally conceded that L. rubescens includes them all, thus proving it to be a variable species. Two or three years after Dr. Lindley named this orchid, it was rediscovered by Hartweg, who was collecting for the Royal Horticultural Society, in Guatemala. Well-grown specimens will produce slender scapes, bearing a loose raceme of six or eight flowers. The latter are two to three inches across, and vary from pure white to the ordinary rosy-lilac hue; the spreading lip is lighter in colour along the side lobes, and also immediately in front of the large marone-purple blotch that occurs at the base. The pseudo-bulbs are ovate, somwhat small and wrinkled, each bearing a single, leathery leaf, oblong-lanceolate in shape. This Mexican orchid is usually best managed in an intermediate house, grown on pieces of tree stem or in hanging baskets. It is not a difficult orchid to manage, but unfortunately it is somewhat scarce, and the large importations of cattleyas and other showy orchids have of late somewhat overwhelmed L. rubescens and other orchids that are not less beautiful. Our illustration represents an inflorescence shown by Mr. W. H. White, the clever orchid grower to Sir Trevor Lawrence, Bart., Dorking, on December 14 last, at the Drill Hall. The flowers were especially fine, and their colour, quite a magenta shade, was more rich than we have ever seen before in this species. On the same occasion Mr. Cragg, gardener to W. Walker, Esq., Winchmore Hill, N., showed a flowering specimen, and in both instances the Orchid Committee granted awards of merit.



LÆLIA RUBESCENS. (Flowers deep rosy-lilac.)

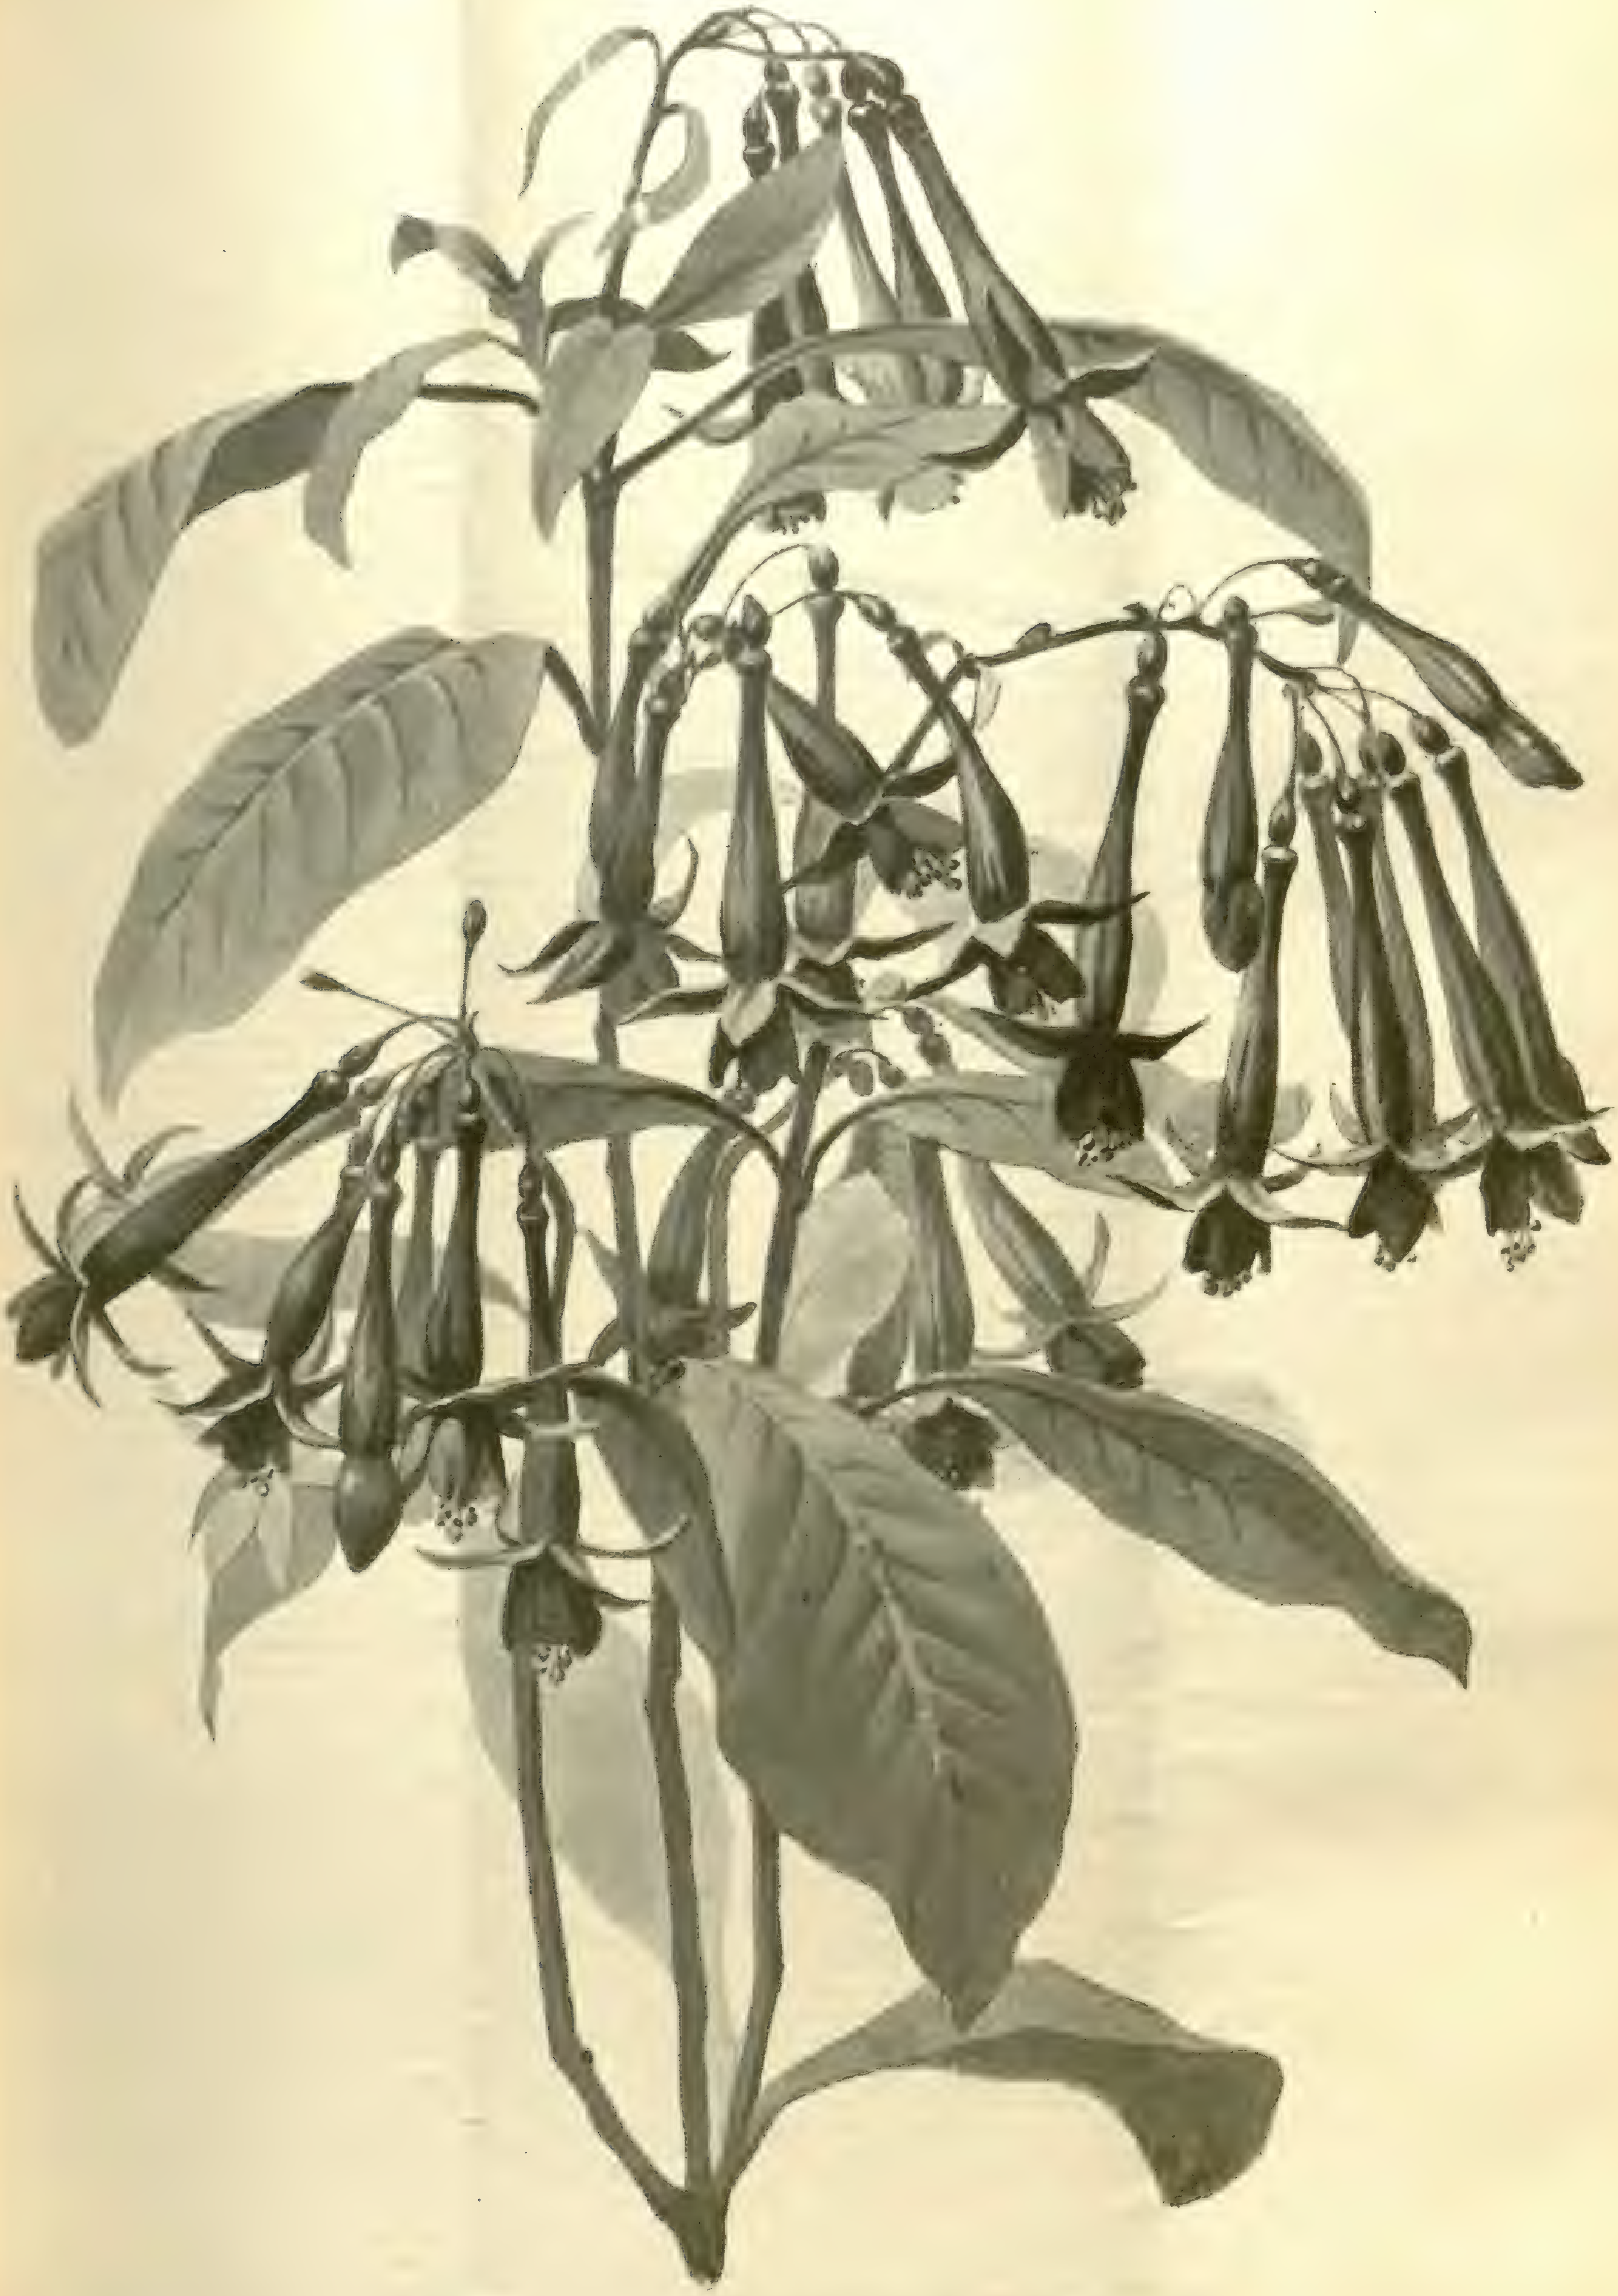
Adiantum Bessonianum.—This fine new maidenhair fern may be aptly described as a glorified form of A. Pacotti. It is a strong grower, sometimes attaining a height of eighteen inches. The fronds are not so dense, in proportion to their size, as those of A. Pacotti. but they have the same general character of numerous and overlapping pinnæ. Mr. James O'Brien introduced the fern from the West Indies, and exhibited it at the R.H.S. meeting of July 14, 1896, when a first-class certificate was awarded it. As regards origin, it appears to be a hybrid between A. trapeziforme and A. tenerum. It is a very handsome fern, and comes true from spores, judging from the small batch of young plants seen recently in Messrs. J. Veitch and Sons' nursery at Chelsea. A full description of this adiantum was given in the GARDENERS' MAGAZINE of July 18, 1896.—A. C. H.

FUCHSIA TRIPHYLLA SUPERBA.

AMONG the many species of fuchsia scarcely one is more distinct than the West Indian F. triphylla. It is a charming plant when well grown, but it needs more warmth than the majority of cultivated varieties. It has slender, graceful branches that terminate in nodding racemes of brilliant cinnabar-red flowers, each bloom being an inch and a half long, and with a much elongated tube. The triphyllate character is not very constant in cultivated plants, but once seen there is never any difficulty in determining the species. The leaves vary from an inch and a half to three inches in length, deep green above, purplish beneath, and remarkable for the manner in which the veins curve from the midrib towards the margin. It is only during the past ten or fifteen years that the species has been cultivated in gardens, and even now it is not by any means a common garden plant, though a batch of specimens flowering in an intermediate house is ever a great attraction. Those who have not hitherto grown the species should make a start with it, for it has received the hall mark of merit—a first-class certificate of the Royal Horticultural Society, and that as long ago as August, 1886.

A strong rival to F. triphylla is its variety superba introduced by Messrs. R. Veitch and Sons, of Exeter. It is a stronger growing plant than the type, having taller growths and larger racemes of blooms, as a reference to the accompanying illustration will pr There is, however, abundant room in gardens for both species variety, for the latter, while being the largest in growth, foliage, race and flowers, is distinct in having crimson-scarlet instead of cinnabar flowers. As in the case of garden varieties of fuchsias, so with variety under consideration, the racemes are so dense that they c the branches to assume a slightly pendent position, and thus a sha specimen is a most graceful object. Certainly those who find so m pleasure in the cultivation of fuchsias should not omit F. triphylla or variety superba.

Pickled Mushrooms.—Take small, freshly gathered button mushroo off the stalks, and rub away the outer skin with flannel and salt. Wash quickly in cold, salted water, drain, and dry them in a soft cloth until no hangs about them. Supposing there should be a quart of mushrooms—mea them after they are prepared—put a pint and a half of the best vinegar saucepan with an ounce of ground ginger, three blades of mace, half an ounce whole pepper, and a pinch of cayenne. When the pickle boils put in the rooms, and let them boil gently for ten minutes, when they will be rather Fill glass jars or wide-mouthed bottles with the mushrooms, and distribute spices and vinegar equally amongst them. When cold tie down in the usual One other most important point to be attended to in pickling is to see that vinegar entirely covers every other ingredient, else the portions which are posed will speedily become mouldy.—HOUSEWIFE.



FUCHSIA TRIPHYLLA SUPERBA. (Flowers crimson-scarlet.)

WORK FOR THE WEEK.

COOL ORCHIDS.

ODONTOGLOSSUM CRISPUM will now be showing flower spikes, and a careful watch should be kept for slugs and snails. Lettuce leaves, sliced potatos, and carrots can be used as traps, and a little fresh bran in small saucers has a great attraction for them ; they should also be diligently searched for at night, using a lamp for their detection. It is a good plan to place the more valuable plants on inverted pots stood in pans filled with water—even then a constant watch is necessary, as the small slugs and snails hide themselves in the potting material. These matters will take up a great deal of the grower's time, but the results fully compensate him for his trouble. Purchasers of imported plants of O. crispum last season will be anxious to see flowers, and to ascertain if any of the spotted forms are amongst them. Flower spikes should not be allowed to remain on the plants for a long period of time, and in the case of well-established specimens it is advisable to cut the spikes after they have been flowering a reasonable length of time. Weakly plants should not be allowed to carry flowers to the detriment of the growths ; most of the buds should be removed, leaving one or two to develop so as to ascertain the variety, but as soon as the flowers are fully open they should be cut off and stood in water in the cool house, where they will retain their beauty for a considerable time. Oncidium macranthum, O. superbiens, and O. undulatum are now showing flower spikes, which often attain a length of from six to eight feet ; these should be trained round neat stakes and be kept close to the glass. These species will also be making new roots, and any that are not showing flower spikes should be repotted if necessary, using a compost of lumpy fibrous peat and clean sphagnum moss, with a good number of thick pieces of charcoal, as the roots of these plants dislike a compressed material ; if the compost is in a sour state around plants that are showing spikes, it may be carefully picked out and the roots resurfaced with new material. Odontoglossum Edwardi and O. ramosissimum come under the same treatment as these oncidiums, and should be grown at the coolest end of the odontoglossum house. The sweet-scented Odontoglossum odoratum is now in flower ; O. pulchellum will also be brightening up the cool house just now, and the latter easily-grown and free-flowering orchid deserves a place in all collections. After passing out of flower they should be repotted or top-dressed if necessary, using plenty of drainage ; and the same compost will suit these plants as advised for oncidiums, with a cool, moist atmosphere all the year round, a shady position, and plenty of water at the roots while growing.

Zygopetalum Mackayi when it has passed out of flower should be repotted or topdressed in a compost of peat, fibrous loam, broken crocks, charcoal, and a little coarse sand ; Z. maxillare and Z. Clayi do best grown on pieces of tree fern stood upright in a flower pot and made secure with crocks and charcoal ; the warmest end of the odontoglossum house will be a suitable place for them, and they should have a plentiful supply of water at all seasons. Cypripedium insigne and its varieties are general favourites because of their easy culture and their value for cutting, the flowers remaining fresh for some weeks. These should now be repotted in a compost of fibrous peat and loam in equal parts and a little fresh sphagnum moss and broken crocks and charcoal intermixed. C. insigne Sanderæ is sometimes grown cool with good results, but I find it does best in a warm house. Lycaste Skinneri and its beautiful white variety should now be attended to, and if repotting is necessary the pots should be half filled with drainage, using the same kind of compost as advised for Cypripedium insigne. At the present time very little fire heat is needed. Give bottom ventilation in accordance with the outside conditions ; if damp and mild the top ventilators may be opened a little on the leeward side and a little fire heat used to promote a circulation of air. Should cold weather prevail close all the ventilators and have the hot-water pipes sufficiently warm to keep the thermometer at the proper degree, also affording a little more moisture both to the roots and in the atmosphere than is required in dull, damp weather.—E. SHILL, *New Hall Hey Gardens.*

STOVE PLANTS.

THE season for repotting will soon be at hand, and in readiness for this operation all the plants should be thoroughly cleansed from all insect pests, so that after repotting they may not need to be disturbed for some time ; any of the advertised insecticides will be efficacious if used according to the instructions issued with them. Have all empty pots washed thoroughly clean, crocks also if at all dirty, and see they are thoroughly dry before using them. Provide plenty of potting sticks or rammers of various thicknesses, also a strong sharpened stick for carefully working out the crocks from among the roots at the base of the old ball, and if it is not possible to remove all the crocks without injuring the roots severely let them remain. It is a good plan to have the various soils mixed at least a few days before using them, and, if convenient, stood in the house where the plants are growing, so that they may become thoroughly warmed through before using, turning it daily the better to attain this end. Many growers commence at a stated time and work through the whole of their stove plants, repotting all before them. This is not a good plan, as the subjects do not all commence growth at the same time. The best time is when each plant is commencing active growth, then the roots take quickly to the new soil, which is soon occupied by active feeders ; if repotted some time before growth is active the soil becomes soured ere young roots are formed. Shabby plants of crotons (codiæums) may have any cuttings they carry removed, and be cut freely back ; stand them in a warm corner, keep rather dry at the roots, and syringe freely overhead. In a short time they will begin to show buds freely, when they may be shaken out, the roots shortened, and repotted into smaller pots, to be afterwards shifted on as pots become full of roots. Old dracænas which may have become bare at the base may have their tops removed and inserted in pots of sand plunged in the propagating case and kept constantly moist ; or they may be rooted by stripping off a few leaves just below where it is desired to root them ; cut a notch halfway through the stem and bind moss around the notch, and if the moss be kept constantly moist roots are formed, the stem may be severed, and the head potted without disturbing much of the moss. The stock of dracænas may be largely increased by cutting up the old stems into short lengths, split down the centre, and inserted in pans of leafsoil and sand ; place a piece of glass over the pan, and stand over the evaporating troughs. The pots for dracænas must be well drained, and the compost most suitable consists of equal parts loam and peat, with a free admixture of sharp sand and charcoal broken small. When the pots are full of roots feeding can be resorted to by means of patent manures sprinkled on the surface and watered in. Crotons delight in a compost consisting of three parts good fibrous loam, one part peat, and one of leafsoil, with sand and broken charcoal added. To each barrowload of this add an eight-inch pot of bone meal and a six-inch pot of some good artificial manure. The loam should be pulled to pieces by hand, and all worms removed at the same time.

Dipladenias that are required to flower in June may now be started. Pot them in equal parts of peat and loam, with plenty of sand and charcoal added. Afford efficient drainage, and give water with care. A moist atmosphere is essential, and, if convenient, afford a bottom heat of 75 to 80 degrees, and a temperature of 65 to 70 degrees. Allamandas and stephanotis may now be encouraged to push into growth by frequent syringings. Should they be in pots or tubs as large as it is desirable to afford them, remove two or three inches of the surface [illegible], and topdress with a mixture of loam, well-decayed manure and sand, giving the old ball a thorough soaking before applying the topdressing. Young plants of gardenias wintered in four-inch pots may now be given a shift into six-inch pots, using a mixture of two parts loam and one part peat, with the addition of [illegible] sand and some well-decayed manure ; pot firmly. Old plants which have [illegible] resting in a cooler house may now be introduced to the stove, and encouraged [illegible] open their flowers ; afford stimulants freely, but not too strong, and keep [illegible] bug in check by a free and forcible use of the syringe. Keep the roof glass of [illegible] houses as clean as possible to allow the ingress of the maximum amount of [illegible]. Damp the paths, walls, and amongst the pots freely, also afford all [illegible] except those in flower a good syringing once a day, preferably about noon. Do not syringe early in the morning, when the temperature is at its lowest point. Very little ventilation is required, it being far better to regulate temperature by checking the fires.—J. TUNNINGTON, *Ripley Castle Gardens.*

KITCHEN GARDEN.

YOUNG lettuces raised from seed sown in boxes early in the last month, will now require pricking off. Where a slight hotbed can be afforded them they will make far more rapid progress than if pricked off into boxes and placed in the houses. Lettuce grown on manure heaps are far more tender than those sown in the autumn and grown under glass through the winter, and if the early varieties are cultivated good hearts may be produced in a short time. They require but little room to grow, as very few outside leaves are made, and if planted four inches apart each way ample space will be allowed. Where a supply has to be maintained, another sowing should now be made, either in a box or on a hotbed, whichever is the most convenient. Cauliflower plants that are being wintered in [illegible] frames must on no account be neglected, as the mild weather has brought them very forward. Where there are signs of these becoming overgrown, it would be advisable to take up the plants and pot them in large sixties or forty-eights. This would not only give them a check, and so prevent them from growing [illegible] large by the time it is safe to plant them out, but would enable them to be planted with a ball of earth attached, which would be a great benefit should the weather be unfavourable when they are transferred to their permanent quarters. Air must be freely admitted on all favourable occasions, in fact, unless there are signs of frost, the lights had better be left off altogether. Young plants raised from seed sown early last month should be pricked off as soon as large enough to handle. Where a quantity are required there would be far less trouble in making up a slight hotbed for them, and in this they could be pricked out at a sufficient distance apart to allow them to remain till they were properly hardened off. If they sh[illegible] become overcrowded before it is safe to transfer them to the open ground, a portion might be drawn and transplanted in a pot, or under handlights, to give an early supply. There is often a difficulty in obtaining young and sweet roots of turnips during the spring and early part of the summer, and but little advan[illegible] is gained by sowing in the open at present, as the soil is too cold to cause a [illegible] growth, and at the first spell of hot weather most of them would bolt. Those that were sown in the open ground in the autumn will soon become tough, therefore some preparations should be made for procuring nice sweet roots as early [illegible] possible. Turnips will not stand much forcing, but a slight hotbed might be made that will generate sufficient heat to cause the seed to germinate freely, and [illegible] tain a little warmth in the soil should cold weather set in. Where a few [illegible] lights can be afforded there will be no difficulty in warding off the rains. Air, however, must be freely admitted on all favourable occasions, as turnips resent a close atmosphere.

Potatos in frames will now be making good progress, and where any of [illegible] haulm is likely to come into contact with the glass, a covering should be afforded whenever there are signs of frost ; but if this can be dispensed with the plants will grow more robust, as there will be a better circulation of air amongst [illegible] leaves. All early sets should by this be placed on their ends that a stout, healthy growth may be produced. If light and air can be admitted so much the better, as these will cause the growths made to be more sturdy. Frost, however, must be excluded, or the consequences will be serious. Where sets have to be procured from a distance, on their arrival they should be spread out thinly. Many people advise planting on a south border or at the foot of a warm wall during this month, but there is nothing gained by so doing. Where the sets can be properly started and planted towards the end of March, young tubers will be ready to lift quite [illegible] early as if planting were done in February. Where, however, there is no convenience for properly doing this, it is far better to plant before growth is too forward, as overgrown sets seldom produce anything like a good crop. If the haulm should appear through the ground before all danger of frost is over [illegible] covering must be afforded to protect them.—H. C. PRINSEP, *Buxted [illegible] Gardens.*

FRUITS UNDER GLASS.

WEATHER conditions should govern to some extent the treatment of [illegible] this time of the year, as, with sunshine by day and fairly mild nights, the temperature may well be raised a few degrees, provided the plants are plunged in [illegible] near enough to the glass to allow just the necessary head-room and no more ; [illegible] if these conditions are not possible, and the weather is wintry and dull, it is best to keep the plants as nearly as possible at a standstill until the sun gains more power, when they can make progress under satisfactory conditions as to [illegible] See that the bottom-heat corresponds with the top-heat ; any rise in the [illegible] should be accompanied by a corresponding rise in the former, and as heat is increased so, too, must the supply of atmospheric moisture be allowed to increase. [illegible] safe temperature for pines in all conditions will be a bottom-heat of from 80 to [illegible] degrees, and top-heat of about 70 degrees, rather less than more. Watering is [illegible] important matter, for though the plants will brook no neglect in this matter, neither must they at any time be over-watered, and a bi-weekly examination of the [illegible] a necessary item in their management. Any that are coming into flower [illegible] be grouped by themselves, as such require to be kept dry overhead, for syringing or subjecting them to drip will certainly result in malformation of the fruits [illegible] possibly, in decay outright. Young stock may be potted on, as occasion [illegible] the compost should consist mainly of fibrous loam which has been stacked [illegible] few months, broken into fair-sized lumps and freed from loose particles, [illegible] should be added burnt soil, a little charcoal, and some crushed bones ; the [illegible] however, had better be left out, and a little mortar rubbish used in their [illegible] unless there is an absolute certainty of their sweetness, for bones that turn [illegible] after application do much injury. The soil should be made thoroughly [illegible] before use, and the plants must be in that intermediate condition, as [illegible] moisture at the roots, known as neither wet nor dry, for if potted in [illegible] condition the results are not satisfactory. Firm potting is a necessity in [illegible] good and quick results with pines, and water should be withheld for several days after potting takes place. Large pots are not needed for growing good pines, and I prefer using those under, rather than over twelve inches diameter, and drain them well. It is too early as yet to begin propagating, and nothing is gained by commencing till March.

The cherry is a very excitable tree, and needs great care in forwarding the crop. The lowest possible temperatures which will keep the trees advancing is the best, and it is well not to exceed 45 degrees at night and a rise to 55 degrees by day, unless the weather is very mild indeed. Afford free ventilation whenever possible, and syringe the trees on bright mornings only; sufficient moisture will be easily supplied by an occasional damping of wall and floor surfaces. Where mixed orchard-house trees are grown in pots it will be necessary now to bring these under cover; each pot should be examined to make sure that the drainage holes are not blocked; and if there is any suspicion of worms in the soil, a good soaking of clear lime water will generally effect a clearance. Where plunging the pots is practised, it is well to thoroughly dust round and under the pots a good application of soot, with a view of preventing the ingress of worms from the soil or other material in which the pots are plunged. Those trees which were not potted in the autumn should have a good top-dressing of some rich material, which should be so placed as to allow of ample supplies of water. As a manurial agent for this work of top-dressing fruit trees in pots, I find nothing so serviceable or so easily applied as malt dust, which may be procured very cheaply in almost any district, and it will be found a very efficacious manure.—J. C. TALLACK, *Livermere Park Gardens.*

HINTS FOR AMATEURS.

AN amateur friend of mine recently took an old house with a neglected garden, and when he came to closely inspect the latter found it full of overgrown gooseberry and currant bushes, bush apple and pear trees, which had run riot, and flower borders which showed they had not been favoured with any attention from the gardener of late. This is by no means an isolated case; the tendency nowadays is for tenants to leave old houses for new ones, because the sanitary arrangements are more perfect and the convenience greater; an old house, generally with a good garden, will remain unoccupied: it becomes a wilderness, then a tenant comes along, rents it, and having a little taste for gardening, is at an utter loss what to do with such a place and state of things.

The first impulse is to dig up everything, destroy what is old and replant. This was what passed through the mind of my friend until he was able to compute something of the cost, and he found it would entail a heavy expense. My advice was to have in a gardener, clear away all weeds and rubbish, the removal of which was necessary; to have the currant and gooseberry trees pruned properly, and thinned out, to cut away some of the branches of the few standard trees; and judiciously thin the bush ones, leaving it to the summer's experience to show what was likely to be of service in the future and what useless. Old-fashioned gardens often contain floral treasures, and it is always wisest to see what is produced before the border is disturbed. There is always time to put in something to make a summer display should it be discovered the border contains little of value. Such fruit trees as are of inferior merit can then be rooted up and destroyed next winter, and others of more value planted. Care should be taken to ascertain what sorts of apples, pears, and plums, do well in the district. Varieties of fruit are sometimes affected by local circumstances of climate; apples and pears that do well in one district will not succeed so well in another, and especially so is this the case with strawberries; and this is how it occasionally happens that fruit trees doing well in one locality and ordered from a distance disappoint one.

That was good advice an old gardener once gave—not to beg or purchase a plant unless there was room for it in the garden. It is a common fault with some amateurs, and gardeners also, who, seeing a plant they like, forthwith purchase it. And unless it should be in satisfaction of a desire to possess some rare species, all purchases—and especially so in the case of a garden of limited extent—should be directed to obtain something in advance of what is already possessed. There was much truth in the remark of an old Lancashire florist: That a plant well worthy of being cultivated takes up no more room than an indifferent one. Never overcrowd; overcrowding is the bane of many gardens cultivated by amateurs. How many attend a bulb or a plant sale, and fascinated by low prices, make purchases they do not actually require. A garden should possess the best of everything it is possible to place in it. It is much better in the long run for an amateur to buy only what he really wants, than to purchase that he does not require, and in all his purchases to consider the requirements of the plant, and especially the position in which it is likely to do best; and then strive to the utmost to so develop it so that it shall become a source of gratification.

R. DEAN.

Apple Lemon Pippin.—"A. D." (p. 67) is quite right in saying that this apple was entered in the Drill Hall flavour competitions recently with not much prospect of success, and it was with no such prospect in view that it was sent, as will be readily imagined by those who know that the same exhibitor sent the first prize dish of Margil to the same meeting. Still, the improbability of an apple or a pear gaining a prize should be no inducement to an exhibitor to keep it back; and my aim, when sending, has been to include as many so-called dessert apples then in season, and of which I have had representative specimens, as the regulations will allow, so that they may be given their proper status, if any, in the promised forthcoming report. The conditions set down for exhibitors have tended to narrow the number of exhibits, and this is unfortunate, as it will leave us in doubt as to the true value of many that have not been shown at all, but those which have been given their chance and failed will figure in the record as not being equal to others then in season. As regards the variety sent being the true Lemon Pippin I can only say that the name is not a modern one, as applied to the apple in question, in this district; for the scions which produced these fruits were taken from a very old, and, locally, well-known tree certainly not less than sixty years old; this has always been known to the oldest inhabitants under the name given—certainly a most appropriate one, the fruits being of true lemon shape and colour.—J. C. TALLACK, *Livermere Park Gardens.*

THE AMERICAN BLIGHT OR WOOLLY APHIS.

PROFESSOR F. V. THEOBALD, of the South-Eastern Agricultural College, Wye, has prepared the following interesting and useful report on the American Blight (*Schizoneura lanigera*), and a related subterranean species (*S. fodiens*), and having regard to the destructive character of these pests, the report deserves the most careful attention.

In most of the old orchards in England this well-known pest may be seen annually, sometimes in great plenty. In the recent plantations, where the trees have been planted under more rational conditions, and kept in a clean and healthy state, very little harm is caused by the woolly aphis, as compared with older orchards, and as seen in many western counties. There are still, however, many apple orchards which, like those of the west country, are extremely picturesque, but which, nevertheless, are a standing danger to apple cultivation, for they are simply nurseries for this and numerous other insect pests which yearly make their appearance in our fruit plantations. The damage caused by Schizoneura lanigera is chiefly to the young wood; the growth is checked by the loss of sap taken by the insects and allowed to escape from the wounds they produce in the tenderer parts of the tree. The results of this attack are large, swollen, cankered patches upon the trunks and branches of the trees, rugosities that are often put down to true "Canker," but which a casual examination would show to be the work of one of the aphides. When first attacked the young bark gradually splits, and open wounds are produced, which in time heal up but leave large depressions, the sides of which form a harbour and safe retreat for the insects during cold and inclement weather. These rugose knots, which often arise as spongy swellings, are caused by the flow of sap to the wounds made by the insects, resulting in an abnormal division and increase of the surrounding cells.

There is little excuse for not coping with this apple enemy, for it is one that is readily seen and speedily destroyed. Wherever the so-called American blight is upon the trees there is nearly always to be seen a quantity of white flocculent wool. This wool is a product of lanigera, a waxy excretion that is passed out of the back of the insect, especially in certain phases of its existence. In the cider-making counties this wool may often be seen hanging down from the boughs in great festoons, and being blown about from tree to tree and orchard to orchard, as we shall see later, carrying with it a cargo of young aphides. So great has been the havoc wrought by this enemy at times that the entire cider crop in certain districts has been lost. This occurred amongst other places in Gloucestershire, where not a gallon of cider was brewed in 1810, owing to the crop failing from woolly aphis attack. Its evil effects can best be seen when it attacks young wood, for then only stunted leaves and blossom, which often shrivel up, are produced.

In Kent the pest seems to be decreasing to some considerable extent, owing, doubtless, to the better state in which the orchards are kept and the repeated "washings" that are employed. It, however, still occasions some considerable annoyance in various parts of the county, notices and inquiries regarding it having been received from most districts. Several fruit growers in the Maidstone area tell me they often are bothered even in young trees by this blight. The eastern part of the county seems to be most free from its attack, yet I have seen it twice there in superabundance, once at Ramsgate and again at Staple. From Mid-Kent and many other parts notices have been sent me, especially in 1894, regarding the supposed attack of lanigera on the roots of apple. Repeated examinations of the root-lice sent as subterranean lanigera have invariably shown that although they were woolly aphides they were quite distinct from the American Blight, S. lanigera, and in all cases the insects could be easily identified as S. fodiens, and a few as Pemphigus lactucæ, as I have pointed out in a previous report.[1] A large consignment was sent me from Paddock Wood in 1894; many of the lice were in little woolly chambers in the soil, whilst others had formed rough lumps on the smaller apple roots, very similar to those figured by Saunders in his admirable work on "Fruit Pests."[2] Numbers of these came above ground and became winged females, clearly distinct from lanigera, and undoubtedly the S. fodiens figured by Buckton in his "Monograph of British Aphides." So far I have been unable to detect any subterranean form of the true American Blight in any part of England. It is not unusual for trees to die under the repeated attacks of this insect. I have seen several such cases; such are usually the result of gross neglect. All apples are attacked by woolly aphis in this country, but perhaps the Ribston Pippin suffers most of all; the Blenheim Pippin, Cox's Orange Pippin, and Lord Suffield also suffer severely. It is especially those apples with a soft rind that are most affected by the attack. I have seen woolly aphis on the Russets, but they are generally exempt from this pest. Certain experiments in Victoria and at the Cape tend to show that apples grafted on the Majetin and Northern Spy stocks are immune from American blight. This apple disease is generally distributed over Europe, America, South Africa, Australia, and New Zealand. It is undoubtedly an European insect, and has been spread from nurseries to the American continent and Australasia, where they have found congenial homes, and there spread from orchard to orchard and state to state with alarming rapidity.

Life History.

The woolly aphis belongs to the section Schizoneurinæ of the Aphididæ, a group which can at once be distinguished by the veination of the wings; the third vein being once forked, whereas in the Aphidinæ it is twice forked, and in the Chermesinæ it is absent. It takes its name lanigera from its covering of wool. Again, lanigera may be told from most other aphides by the entire absence of those curious appendages which are generally present in this group, namely, the "cornicles," or honey-tubes, they being represented by two spots. The apterous female is oval, dark brown, and is covered with a small quantity of wool; eyes very small, antennæ and legs very short and dark reddish-brown to black. These apterous females, which are often surrounded with a number of little pellucid globules, live during the winter in the crevices of the bark, and are not affected by frost. In the spring they produce small pale reddish lice, which excrete a quantity of wool from their backs, the threads forming long spiral filaments. Occasionally winged females are produced, but they are unusual; they are chocolate-brown in colour, and have the veination peculiar to the Schizoneuræ, and yet distinct from other species of the group. Their antennæ are short, the wings are ample and rounded at their apices. The broad cubitus ends in a large brown stigma; costal vein once forked, veins black. The winged viviparous female appears from July to September, and is not uncommon, Mr. Smith, of Loddington, informs me, in Kent orchards. I have not been fortunate enough to observe it as yet. The winged female is preceded by the pupal stage, which is dull brown with yellow legs, antennæ and wing cases, and rounded in form.

These winged females produce oviparous females, which are destitute of a mouth or rostrum, and thus are unable to take any nutriment. The oviparous female is reddish-yellow and very small, seldom larger than ·003 of an inch. There are males also produced in the autumn (also arostrate), these fertilise the oviparous females, which deposit a single ovum each in crevices of the bark of the apple trees, so as to ensure the continuity of the species. The existence of a winged viviparous female was doubted by Hausmans and Knapp, whilst Lichtenstein observed them swarming in the orchards of Southern France. Buckler received some from the latter authority in September, 1878, from Montpellier, and since then numerous notices of them have appeared in Kent and elsewhere in England, and also in America.

[1] Insect Pests in 1894, page 4.—F. V. T.

[2] Insects Injurious to Fruits, page 14.—Saunders.

The Probable Origin and Present Distribution.

The name "American Blight" is given to it on account of its supposed origin in that continent. This is strongly protested against by Dr. Asa Fitch. It was known in Europe in 1787, and was said by Serville and Amyot to have been imported from England to the Continent. Its origin in England, according to Sir Joseph Banks, was near London, in a nursery which was partly stocked from America. The first serious loss from this pest was in the vicinity of the metropolis. Gradually it spread into the western counties, where by 1810 it was sufficiently abundant to ruin the cider crop in Gloucestershire. Every year it spread further and further over England, until it is now found in nearly every apple district. I have been unable to detect it except very occasionally in Wales. In 1818 it was doing damage around Paris, and by 1822 it was very common in the departments of the Somme, Aisne, and Seine. In Germany there are records of it in 1801, and in Belgium in 1812. In Italy it is still scarce. American orchards now teem with it, especially in those districts with a cool climate, notably the New England States. New Zealand, the Cape, and Australia are also infested to a serious extent in places, especially the former colony. There is little doubt but that they were derived in the latter places from England in imported stock.

Does *S.* lanigera have a *S*ubterranean Generation?

This is a question about which much diversity of opinion exists. We know that lanigera, as pointed out by Buckton, often attacks the stem of the tree low down and close to the ground. These are exactly similar forms to those we find on the branches and twigs, and cannot be considered a subterranean race. It is, however, stated on such good authority as Goureau, Saunders, Riley, and Thomas, that there is a subterranean form of lanigera upon apple roots, just in the same way as we see in the vine phylloxera. Buckton had not observed this in England, but says, "There seems no good reason to doubt that it does exist occasionally." I have made repeated inquiries and searches for this ground form, and have never been able to detect it. Yet very often white, woolly patches and galled swellings may be found on apple roots. In all cases the culprits I examined have proved to be S. fodiens, now and again, Pemphigus lactucae. The former I have found abundantly on several occasions forming swellings and white nidi on and around apple roots and rootlets. Lactucae makes similar white nidi in the ground, especially in winter and spring, at the roots of lettuce and various plants. I have never seen this aphis forming galls, but have taken it on apple rootlets. Several samples of fodiens have reached me, with notes regarding the supposed American blight attack on the roots. In breeding the same the winged generations soon dispelled this notion. I can only add that all the cases notified to me in England of this root attack have been caused by one or other of the two aphides named. I at first thought the apterous lice sent me might be a ground form of lanigera, and was not convinced to the contrary until the winged generations came above ground.

S. fodiens (Buckton) may be identified by the following features: The apterous female is globular and shiny, yellowish and mealy, head dark brown; antennæ bluish-brown, finely ringed and cupped as in lanigera; eyes absent—no cornicles, legs bluish brown. The pupa has eyes and is reddish-brown, with short dark rostrum. The winged female has a slaty-grey abdomen; head, thorax, and legs shining black; wings fuscous, coarsely punctured; stigma yellow; cubital vein once forked and not united with cubitus; two oblique veins to hind wings. Numbers of this species live together in nests in the ground, lining them with white fluffy cotton. The young larvæ that arise from the winged females are vermiform. Buckton thinks these are the sexual forms; they appear in the autumn. Buckton states that he has taken this species plentifully in November on black currant roots at Haslemere from four to six inches underground. That this species and probably P. lactucae occasion severe loss in apple trees cannot be doubted. Many cases of apples failing have been traced to woolly lice on the roots, and in all cases examined by myself, whether in the earth surrounding the roots or in "galled" roots themselves, only the two species here mentioned have so far occurred. Possibly subterranean American blight forms do similar damages, for we cannot doubt their existence abroad when such competent observers state they know the attack well, but I think in England we want further evidence of its existence. This is a point of some economic importance, for if there is a migration, as sometimes stated, from trunk to root and vice versa, we might check to some extent their ravages.

Natural Enemies.

Although aphides have generally many natural enemies amongst members of their own class, little good is done by them in regard to lanigera. Possibly the woolly excretions and globules with which the American blight is surrounded may keep these useful parasites and carnivorous foes off. I have seen, nevertheless, the larvæ of the Coccinellidæ, or lady birds, devouring them and their wool ravenously, and have known some badly infested trees cleared by them. During the present year I had a tree cleared by placing forty "niggers," as the larval lady birds are called, upon it, in less than a week, cleared far more thoroughly than by any insecticide. Larvæ of several species of Syrphidæ, or hover flies, also sometimes feed upon them, but not to the extent that they do upon other aphides. Only once have I seen them in any number amongst the woolly aphis. The lace-wing flies (Hemerobidæ) may also devour them, whilst the Ichneumonidæ now and again parasitise them to a small extent. I have also found a small dipterous larva of the genus Pipiza feeding on the root species. Riley also records Pipiza radicum feeding on the ground American Blight in America. I have also seen various spiders and Phalangidæ devouring them, and a species of Nemacoris, one of the hemiptera-heteroptera.

Amongst birds the Blue Tit (*Parus cæruleus*) is far the most beneficial in orchards attacked by this pest. One can see these beautiful little creatures hunting around the boughs and trunks in the winter and clearing off this noxious insect wholesale. Without these "feathered friends" we should suffer much more severely than we do at present, and they should be strenuously protected in all fruit orchards, where the inestimable good they do far outweighs the slight loss they may occasion by destroying a few buds, many of which are already infested with some insect or mite. Frost has no effect upon this insect. The aphides have been found active on the trees during some of the sharpest frosts we have experienced in these islands.

Prevention and Remedies.

This blight is especially to be seen in badly kept orchards, where the trees are set close together, the trunks and boughs covered with moss and lichens and kept in general unhealthy surroundings. Needless to say these should be remedied as quickly and as far as possible. The lichens and moss should be scraped off or burnt off during the winter with the following wash: Ten pounds of caustic soda, ten pounds of caustic potash, to one hundred gallons of water. Not only will this destroy the lichens and moss, but also the lice and insects, and also most of the ova laid in and upon the vegetable growth on the trees and their bark. A tree washed during the winter in such a way will soon appear quite noticeable amongst the rest, it becoming quite black, and the rind and bark perfectly clean and healthy and in nowise damaged by the burning action of the wash. In many cases scraping the bark has to be resorted to, so as to get off all the rough and loose bark, beneath which the insects go in cold weather. It is also essential to clean off this superfluous bark to obtain a smooth surface, so that the whitewash for the trunks will take evenly. With regards to painting the trees, any thick wash with a base of soft soap will be serviceable. Perhaps the following is as good as any: One pound of soft soap, one gallon of lime, a small quantity of size, mixed with sufficient warm water to form a thick whitewash. Simple soft soap and warm water is sufficient, however, rubbed over the trunks with a scrubbing brush. We must remember that it is the soft soap that destroys the aphides in the various washes employed by blocking up the spiracles; the other ingredients may improve the wash, but they are quite unessential as far as all plant lice may go.

In whitewashing the trees great care should be taken to go right down to the ground, as it is not at all unusual to find the blight congregated as low down as the surface. In destroying them during the summer and when they are on the young wood, washing to be effectual should be commenced directly the first traces of the white wool appear. Prior to using the soft-soap wash, the trees attacked should be well drenched with plain cold water sent with some force amongst the blight by a garden engine. This will be found to loosen and destroy much of the wool and thus expose the aphides to the deleterious effects of the soft soap afterwards, otherwise the soft soap holds to the wool and does not touch the insects. The effect of thunder showers and heavy rains is most marked upon this blight, clearing it off far more successfully than any artificial washings. As much as sixteen pounds of soap to the hundred gallons of water should be used as long as one finds the machine does not "block."

With regard to the attack of S. fodiens and possibly S. lanigera on the roots, more difficulty in dealing with the pests will be found. One point should claim every fruit grower's attention, and that is to examine the roots of all young stock that comes from the nurseries. Any traces of the galled patches or white wool upon the roots would soon be seen by a casual observation. The examination should nevertheless be very complete, as one female may soon establish a colony. Should any be found, steps should be taken to destroy it before the trees are planted, and thus save much further annoyance. This can be easily done by dipping the roots into warm water and strong soft-soap for a minute or two, and moving them about so as the whole comes in contact with the wash, and so destroying the subterranean pests. A certain amount of good may be done by exposing the roots in trees that are not flourishing, and if any sign of this blight is upon them a good drenching of soapsuds, so as to soak all the soil and the crevices of the roots, as recommended by Dr. Asa Fitch, would be advisable. Miss Ormerod, in her valuable work on injurious insects, states that the draining of stables has been recommended and "is said to cure the evil."

The introduction of "Blight-proof" stocks, such as the Majetin and Northern Spy, mentioned by Mr. French in his "Report on the Injurious Insects of Victoria," and by Mr. Lounsbury in this year's Cape of Good Hope report, would doubtless be beneficial as far as the ground attack goes. Of course the grafts would be just as liable to attack. Of course if there is a migration of S. lanigera between the trunk and roots, which is probable, when we find statements to that effect by Miss Ormerod, Mr. Whitehead, and numerous American authorities, bands of tarred hay or cloth around the trees, placed close to the ground, would stop the migration. But it is well first to find out if those root forms are S. lanigera, or the species recorded here and elsewhere. Various other substances have been mentioned as destroying this blight, such as tobacco leaves boiled in water—one pound of tobacco to six gallons of water; kerosene and paraffin emulsions, and various patent insecticides, but none are successful unless soft soap is included in the wash, and that alone is sufficient, hence none of these various insecticides have been mentioned. If desired the regular proportion of quassia may be added to lend its cleansing effects to the leafage, &c. The protection of the natural enemies mentioned should also be paid attention to, and every encouragement given for their increase.

Cell Growth.—In a recent lecture Professor Ray Lankester considered the evidences of the activity called life in the protoplasm of the cell. This, he said, is difficult to observe directly, but it could be inferred in various ways. Cells were noticed in different stages of development, or they were seen to grow in size or to divide into parts. The enormous number of cells that built up animals and plants had originated from other cells by division, and could be traced back to a nucleated corpuscle termed a fertilised germ cell. Another evidence of this vital activity could be found in the movements which were visible in some living cells. Among these he mentioned the amœboid movements exhibited by many cells floating in animal fluids, the granule-streaming to be seen in the cells of the hairs of the spiderwort, the cyclosis of green corpuscles often visible in plant cells, the contraction and expansion of vacuoles, and the ciliary movements exhibited in [illegible] animals by threads of protoplasm extending beyond the cell. All these movements of protoplasm were probably to be regarded as due to chemical changes. The lecturer proceeded to make some further remarks about the structure of a typical cell. After describing the Linin and Chromatin threads and referring [illegible] nuceolus, he discussed the function of the nucleus. This was at first thought [illegible] of great importance, then it was discredited, but of late years it had again come [illegible] be recognised as a very important part of the cell. That such was the case [illegible] been proved by cutting into pieces some of the larger unicellular animalcules which could be manipulated under the microscope. If one of these was cut [illegible] pieces in such a way that one portion contained a nucleus, while the other did [illegible] it was found that, whereas the latter, though it lived for many days, showed [illegible] growth and eventually died, the former recovered itself and grew to the [illegible] shape of the original animalcule. The experiment thus afforded evidence [illegible] the nucleus controlled the growth and nutrition of a cell. Were there [illegible] the simpler forms of life that did not possess a nucleus? That was a [illegible] matter. In some cases observation failed to discover a proper nucleus. The conclusion probably was that no cells were devoid of nuclear substance, which [illegible] some low forms was diffused through the protoplasm in a pulverulent condition.

EXHIBITIONS AND MEETINGS.

OXFORDSHIRE CHRYSANTHEMUM AND FRUIT SOCIETY.

THE thirty-fifth annual general meeting was held at the Roebuck Hotel, Oxford, on Tuesday evening, January 25. Mr. Alderman Cooper presided, there being forty-one other subscribers present. The report, which had been printed and circulated, stated that the society had had a most successful season, the best for the past five years, the show held on November 11 last being remarkable for the large number of specimen blooms and nearly three hundred dishes of high-coloured apples, &c. The vegetable classes, introduced for the first time, contained choice collections, but the competition was not as keen as was hoped for. The accounts showed that the receipts for the period had been £92 2s. 3d., and exceeded the payments by £6 16s 4d., thus enabling the committee to clear off £6 15s. debt from 1896, and start afresh with a small cash balance of £1 12s. Before passing the accounts a lively discussion arose (a) as to the definition of the term "Amateur"; (b) what powers do committees possess in using the funds for luncheons; and (c) the power to offer prizes for vegetables without a special authority in the rules; the result of the arguments was that [the new committee are to define an "amateur" in the schedule for the current year, and either to amend the rules giving them power to offer prizes for vegetables, or obtain the funds as special donations. G. H. Morell, Esq., M.P., was elected president; Montague Wootten, Esq., treasurer; the Rev. R. H. Charsley, hon. secretary; Mr. W. Greenaway, acting secretary (thirty-first year); W. S. Carver, Esq., auditor; and Messrs. G. Salter (thirty-sixth year), J. Fortescue, M. Jefferies, T. W. Jacobs, G. Neal, H. Smart, J. Skuse, and L. McGreal as committee. The next show was fixed to be held on the second Thursday in November.

THAME HORTICULTURAL SOCIETY.

The forty-eighth annual meeting was convened on the evening of January 25 in the Council Room, Town Hall. P. J. D. Wykeham, Esq., presided over a goodly attendance of members. The secretary (Mr. C. J. Plim) submitted the report, which stated that the show held on September 2 last was not a success, although held in conjunction with a fire brigade competition. The weather, the day and night previous, was stormy, blowing down the tents, but by a special effort the exhibition was opened at the usual hour; still the attendance was much less than the average, causing a loss on the year of about £34. The entries for the show manifested a considerable falling off, owing to a number of exhibitors having ceased to compete. The chrysanthemum show held on November 11 was well patronized, the chief attraction being the music, as the exhibits were but few, and the question of continuing the winter event would have to be seriously considered. The president was re-elected, as were also ten vice-presidents; Mr. J. E. D. Ostrehan, treasurer; Mr. Plim, secretary, and a committee of fourteen. Mr. S. Walker resigned the office of collector, which he had held for a quarter of a century, the duties being relegated to the secretary. It was decided to discontinue the chrysanthemum show, and substitute a live-stock exhibition to be held in conjunction with the September flower show.

HEADINGTON HORTICULTURAL SOCIETY.

The seventeenth annual meeting was held at the British Workman Institute, under the presidency of R. H. Dockray, Esq., Stoke House. The report, submitted by the secretary (Mr. W. Greenaway) congratulated the members on a fair record of success during the past year; the income had been £110 9s. 2d., which sum exceeded the payments by £2 18s. 3d. Referring to the show held on August 2 last, it pointed out that the competitive display was very largely helped by a number of exhibits not for competition, foremost of these being the wonderful arrangement of lilies, tea, garden, and perpetual roses set up in vases, wreaths, chaplets, and single and triple trusses of blooms; a grand bank of tuberous begonias sent by Thomas Arnall, Esq.; and a collection of picotees and carnations from Mr. G. Chaundy, jun. The main features of the competition were the groups of plants for effect, roses, table decorations, bouquets of perennials and annuals, hardy fruits, and, and for a somewhat dry season, the grand collections of allotment produce. The attendance proved the largest yet experienced. Colonel Hoole was elected president; R. H. Dockray, Esq., treasurer; Mr. W. Greenaway, secretary: the committee to include Messrs. A. Griffin, J. Stringer, C. Bodimeade, H. Parker, G. Tolley, W. T. Mattock, J. R. Mattock, C. Ricketts and J. Skey. The next show was fixed for Monday, August 1. A vote of thanks to the chairman concluded the business.

BANBURY CHRYSANTHEMUM SOCIETY.

The annual meeting was held at the White Lion Hotel. The Mayor (A. Fairfax, Esq.) presided. From the report submitted it appeared that the show and musical addenda on November 17 and 18, proved an unqualified success, resulting in a financial gain of £12 1s. 11d., and giving the society a cash balance in hand of £27 3s. 3d. Lord North was re-elected president; Mr. S. J. Mawle, treasurer (in the place of Mr. H. A. Strange, resigned); Mr. W. H. Walkely, secretary; and Mr. F. E. Bushy, assistant secretary; a committee of fifteen members was elected by ballot. The chairman and several others volunteered special prizes, and it was decided to hold the show on November 16 and 17 next.

LIVERPOOL HORTICULTURAL ASSOCIATION.

The nineteenth annual general meeting of the above association was held in the Free Library, William Brown Street, on Saturday evening last, Mr. T. Foster, vice-chairman, presiding, in the absence of Mr. T. White through indisposition. The financial position of the society showed a slight falling off as compared with its state twelve months ago, the holding of the summer show contributing principally to this. Several new members were elected on the committee. Mr. William Dickson, 7, Victoria Street, was re-elected secretary, and Mr. G. Blackmore, sub-treasurer. The number of exhibitions for the present year will be two, the spring show to be held about the end of March, and the autumn one in November. A vote of thanks to the chairman concluded the proceedings.

J. V. T.

WINDSOR CHRYSANTHEMUM SOCIETY.

The annual general meeting of this society was held at the Castle Hotel, under the presidency of C. Sainty, Esq. There was not a large attendance. The report stated that the result of the year's work had given a cash balance of £5 3s.

NEW BOOKS.

The English Tulip. Price 1s. 6d. (Messrs. Barr and Sons, 12 and 13, King Street, Covent Garden, W.C.)—Under the title of the "English Tulip and its History," Messrs. Barr and Sons have published the papers read at the Conference held by the National Tulip Society in the Royal Botanic Society's Gardens, May 12, 1897, and thereby placed the lovers of the English Tulip under a great obligation to them. The papers read at the Conference were: "The History and the Properties of the Florist's Tulip," by Mr. J. W. Bentley; "Seed and Seedlings of the Florist's Tulip," by the Rev. F. D. Horner; and "The Cultivation of the Florist's Tulip," by Mr. C. W. Needham; and the three are given in full in the brochure before us.

Comprehensive Guide to Printing and Publishing. (W. H. and L. Collingridge, *City Press*, 148 and 149, Aldersgate Street, E.C.)—This excellent guide was issued some years since by Messrs. W. H. and L. Collingridge, who, from long experience, were persuaded that a manual containing detailed information on subjects connected with printing and publishing would be useful both to authors and persons engaged in commercial and professional pursuits, and its value is indicated by the fact that it has passed through ten editions. The eleventh edition, which is now before us, has been thoroughly revised and greatly improved, and can hardly fail to greatly enhance the popularity of the work. Everything relating to preparing, printing, and publishing books, and other publications, is fully described, and the advice throughout is so clearly stated that even those with but little experience of literary work will have but little difficulty in acting upon it. The manual contains much that should be useful to those who contribute to periodical literature, and we would direct special attention to the following extract: "There are writers who, though fully aware of the objectionable characteristics of their handwriting, can no more do away with them entirely than they can rid themselves of their idiosyncrasies. Hence the importance of their attention to our suggestions respecting the careful preparation of 'copy.' The neglect of the simple precaution of dotting i's and crossing t's, and plainly writing u's and n's—and, we must add, of placing the dots directly (vertically) over the i's—occasions numerous errata, which sometimes escape notice until it is too late to correct them. Many gentlemen who write for the Press fall into an error that appears inconsistent even with common reasoning, viz., that the worse the manuscript is written, the more likely the work is to be correctly printed; for, say they, the more difficulty the printer meets with in reading it, the more pains he is obliged to take to understand the subject; and, of course, he will print it more accurately than if he could pass it over in a cursory manner. In refutation of this prevalent error, we would ask those gentlemen if they have never received letters from their friends, so hastily and carelessly written, that their utmost efforts to decipher every word have been baffled, although they might arrive at the general meaning of the whole? (We have ourselves seen letters which set at defiance all attempts to read them.) We would ask those gentlemen whether, in examining ancient MSS., they have not often been perplexed in making out the subject, and, after all their endeavours, have at last risen from the task in many instances rather guessing at the meaning than being certain of it. Even so, and worse, is the case of the printer with ill-written manuscript, who frequently is ignorant of the subject on which he is engaged. How, then, is it probable that he should produce a proof as correct as if the manuscript were written in a fair legible hand? It is neither probable nor possible." In the case of periodical literature the copy is overhauled by the editor, who, although endowed with more than the usual amount of patience, consigns considerable quantities of MSS., dealing with subjects of interest, to the waste-paper basket, simply because they are so badly written that no compositor could decipher them without extreme difficulty.

Knowledge. Price 6d., monthly. (Knowledge Office, 326, High Holborn, London W.C.)—The issue of this excellent magazine for the current month is so thoroughly good throughout as to suggest that the volume for the current year will surpass in interest and utility even that of 1897. Science, literature and art receive full attention in the pages of "Knowledge," but science somewhat predominates, and as it is dealt with in an interesting manner, those who are desirous of keeping themselves well informed upon scientific questions without engaging in the serious study of the several branches of science could have no more useful periodical than this. Natural history is well represented, and the British Ornithological notes are invariably of much interest, those for the current month being of special interest. In the January issue Mr. A. B. MacDowall, M.A., asks, "Is weather affected by the moon?" and in his reply he contends that a certain definite relation to the moon's phases appears from time to time and persists perhaps half a year or more, and states that the half-year ending with November last is a good example.

Pastures and Pasture Plants. By WILLIAM TOOGOOD. (Macmillan and Co. (Limited), St. Martin's Street, London, W.C.)—Having regard to the immense importance of pastures in the economy of the farm at the present time the publication of this work is most opportune, and we have much gratification in stating that the work is one which those responsible for the management of grass lands may consult with advantage. The opening chapter is devoted to the preparation of the land and the application of manures previous to its being laid down to grass, and the details are so arranged that information upon any particular point can be found with the least possible difficulty. In the second and third chapters the grasses and leguminous plants most useful in the formation of pastures are described and their peculiarities pointed out. In the remaining sections of the work, details relating to the sowing of seeds, the care of new and established pastures, and hay making, are fully described, and the advice is clear and concise throughout. The work is illustrated, and the numerous figures materially assist in the elucidation of the text.

The Culture of Vegetables and Flowers. By SUTTON and SONS. Price 5s. (Simpkin, Marshall, Hamilton, Kent, and Co., 32, Paternoster Row, London.)—On the appearance of the first edition of this important work, we felt it our duty to speak of it in appreciative terms, and to counsel our readers to purchase it, and make themselves familiar with the contents of the well-stored pages. We are therefore gratified to receive a copy of the seventh edition, for no better evidence could be desired that our advice has been acted upon, and our opinion with regard to its utility fully endorsed by those engaged in gardening pursuits. The work has been revised with a view to place it abreast with the present state of our knowledge of the cultivation of vegetables and flowers from seeds and roots, and can be strongly recommended to both amateur and practical gardeners. The chapters on the chemistry of garden crops, and on insect pests and plant diseases, should receive careful attention, as, with an acquaintance with the information embodied in them, the cultivator will experience much less difficulty in maintaining the fertility of the soil of his garden and keeping his crops free from insect and fungoid attacks than will those whose knowledge is limited to an acquaintance with practical details.

HORTICULTURAL EXHIBITIONS AND MEETINGS IN 1898.

MOST of our readers will at this season desire to make up, as far as possible, a list of the various horticultural exhibitions and meetings for the present year, and to enable them to do so we append as complete a list of fixtures as possible. We wish to express our obligations to those secretaries who have so kindly furnished us with dates, and we hope that others will forward, as soon as decided, similar particulars of the society to which they belong. In this matter the large general body of our readers may also help us and each other considerably by forwarding dates of exhibitions that come under their notice.

FEBRUARY.

Tuesday, 8.—Royal Horticultural Society: Committees meet and Annual General Meeting.

Saturday, 12.—Royal Botanic Society: General Meeting.

Monday, 14.—Smoking Concert in connection with the N.C.S. at Anderton's Hotel, E.C.

Thursday, 17.—Linnean Society.

Friday, 18.—Royal Gardeners' Orphan Fund: Annual Meeting and Election.

Thursday, 24.—Kew Guild: Annual Meeting at eight p.m.

Monday, 28.—National Chrysanthemum Society: Annual Meeting.

MARCH.

Tuesday, 1.—Scottish Horticultural Association.

Thursday, 3.—Linnean Society.

Tuesday, 8.—Royal Horticultural Society: Committees meet.

Saturday, 12.—Royal Botanic Society: General Meeting.

Monday, 14.—United Horticultural Benefit and Provident Society: Annual Meeting at Caledonian Hotel, eight p.m.

Tuesday, 15.—London Fruit and Potato Trades Benevolent Society: Annual Dinner.

Thursday, 17.—Linnean Society.

Tuesday, 22.—Royal Horticultural Society: Committees meet.

Wednesday, 23.—Torquay Gardeners' Association: Spring Show.

Saturday, 26.—Royal Botanic Society: General Meeting.

Tuesday, 29.—Shropshire Horticultural Society: Spring Show. Southampton Horticultural Society (two days).

Wednesday, 30.—Royal Botanic Society's Spring Show.

APRIL.

Tuesday, 5.—Scottish Horticultural Association.

Wednesday, 6.—Royal Caledonian Horticultural Society's Spring Show (two days).

Thursday, 7.—Linnean Society. Royal Horticultural Society of Ireland: Spring Show.

Saturday, 9.—Royal Botanic Society: General Meeting.

Tuesday, 12.—Royal Horticultural Society: Committees meet.

Saturday, 16.—Ghent Quinquennial Exhibition (open till April 24).

Wednesday, 20.—York Spring Flower Show. Royal Gardeners' Orphan Fund: Annual Dinner.

Thursday, 21.—Linnean Society. Newcastle Spring Show (two days).

Saturday, 23.—Royal Botanic Society: General Meeting.

Tuesday, 26.—Royal Horticultural Society: Committees meet.

MAY.

Tuesday, 3.—Scottish Horticultural Association.

Thursday, 5.—Linnean Society.

Saturday, 7.—Royal Botanic Society: General Meeting.

Tuesday, 10.—Royal Horticultural Society: Committees meet.

Friday, 13.—Royal Botanic Society: Lecture.

Wednesday, 18.—York Florists' Exhibition.

Friday, 20.—Royal Botanic Society: Lecture.

Saturday, 21.—Royal Botanic Society: General Meeting.

Tuesday, 24.—Linnean Society's Anniversary Meeting.

Wednesday, 25.—Temple Show (three days). Bath and West of England Society's Exhibition at Cardiff (five days).

JUNE.

Thursday, 2.—Linnean Society.

Friday, 3.—Royal Botanic Society Lecture.

Tuesday, 7.—Scottish Horticultural Association.

Wednesday, 8.—Royal Botanic Society's Summer Show. Gardeners' Royal Benevolent Institution: Annual Dinner.

Friday, 10.—Royal Botanic Society Lecture.

Saturday, 11.—Royal Botanic Society: General Meeting.

Tuesday, 14.—Royal Horticultural Society: Committees meet.

Wednesday 15.—Grand Yorkshire Fête and Gala (three days).

Thursday, 16.—Linnean Society.

Friday, 17.—Royal Botanic Society: Lecture.

Monday, 20.—Royal Agricultural Society's Show at Birmingham (four days). Royal Oxfordshire Horticultural Society.

Wednesday, 22.—Jersey Horticultural Society's Rose Show.

Thursday, 23.—National Rose Society's Show: Conference at Bath.

Friday, 24.—Royal Botanic Society: Lecture.

Saturday, 25.—Royal Botanic Society: General Meeting. Windsor and Eton Rose Show.

Tuesday, 28.—Royal Horticultural Society: Committees meet. Southampton Horticultural Society (two days).

Wednesday, 29.—Croydon Horticultural Society. Richmond Horticultural Society.

Thursday, 30.—Royal Horticultural Society of Ireland.

JULY.

Saturday, 2.—National Rose Society at Crystal Palace.

Tuesday, 5.—Scottish Horticultural Association.

Wednesday, 6.—Borough of Hanley Floral Fête (two days).

Thursday, 7.—Norfolk and Norwich Rose Show.

Saturday, 9.—Royal Botanic Society: General meeting.

Tuesday, 12.—Royal Horticultural Society: Committees meet. Wolverhampton Floral Fête (three days).

Wednesday, 13.—Newcastle Summer Show.

Thursday, 14.—National Rose Society at Halifax. Salterhebble and District Flower Show. Jersey Gardeners' Floral Fête. Canterbury Floral Fête.

Saturday, 23.—Royal Botanic Society: General Meeting.

Tuesday, 26.—Royal Horticultural Society: Committees meet.

Wednesday, 27.—Brighstone (Isle of Wight) Flower Show.

AUGUST.

Monday, 1.—Northampton Floral Fête (two days). Headington Horticultural Society.

Tuesday, 2.—Scottish Horticultural Association.

Wednesday, 3.—Ancient Society of York Florists: Carnation Show.

Tuesday, 9.—Royal Horticultural Society: Committees meet.

Wednesday, 10.—Bishop's Stortford Horticultural Society. Hastings and St. Leonard's Summer Show.

Saturday, 13.—Royal Botanic Society General Meeting.

Wednesday, 17.—Shrewsbury Floral Féte (two days). Shanklin (I. of W.) Summer Show.

Thursday, 18.—Jersey Horticultural Society. Niton (I. of W.) Horticultural Society. Abingdon Horticultural Society.

Friday, 19.—Devon and Exeter Horticultural Society.

Tuesday, 23.—Royal Horticultural Society: Committees meet. Royal Oxfordshire Horticultural Society.

Wednesday, 24.—Harpenden Horticultural Society.

Thursday, 25.—Ellesmere Horticultural Society. Grandpont and South Oxford Summer Show.

Friday, 26.—Royal Horticultural Society of Ireland.

Saturday, 27.—Worsley Flower Show.

SEPTEMBER.

Friday, 2.—National Dahlia Society at Crystal Palace (two days).

Tuesday, 6.—Royal Horticultural Society: Committees meet. Chrysanthemum and Dahlia Show, Royal Aquarium (three days). Scottish Horticultural Association. Durham Floral Society.

Wednesday, 7.—Ancient Society of York Florists: Dahlias.

Monday, 12.—United Horticultural Benefit and Provident Society: Committee Meeting.

Wednesday, 14.—Royal Caledonian Horticultural Society (three days).

Tuesday, 20.—Royal Horticultural Society: Committees meet.

Monday, 26.—National Chrysanthemum Society: General Committee.

Thursday, 29.—R.R S. Fruit Show at Crystal Palace (three days).

OCTOBER.

Tuesday, 4.—Scottish Horticultural Association.

Tuesday, 11.—Royal Horticultural Society: Committees meet. National Chrysanthemum Society (three days.)

Monday, 24.—National Chrysanthemum Society: Floral and General Committee Meetings.

Tuesday, 25.—Royal Horticultural Society: Committees meet.

Monday, 31.—National Chrysanthemum Society: Floral Committee.

NOVEMBER.

Tuesday, 1.—Scottish Horticultural Association. Croydon Chrysanthemum Show (two days). Torquay Chrysanthemum Show (two days). Southampton Chrysanthemum Show (two days).

Wednesday, 2.—Isle of Thanet Chrysanthemum Show (two days). Kent County Chrysanthemum Show (two days). Dorchester Chrysanthemum Show (two days). Jersey Chrysanthemum Show (two days). Wolverhampton Chrysanthemum Show (two days.)

Thursday, 3.—Exeter Chrysanthemum Show (two days). North Peckham Chrysanthemum Show (four days).

Saturday, 5.—North of Scotland Root, Vegetable, and Fruit Show.

Tuesday, 8.—Royal Horticultural Society: Committees meet. National Chrysanthemum Society (three days). Highgate Chrysanthemum Society (three days). Birmingham Chrysanthemum Society (three days). Yeovil Chrysanthemum Society (two days). Oxford Chrysanthemum Society.

Wednesday, 9.—Bournemouth Chrysanthemum Society (two days). Jersey Chrysanthemum Society (two days). Wisbech Chrysanthemum Society (two days). Royal Horticultural Society of Ireland Chrysanthemum Society.

Thursday, 10.—Harrogate Chrysanthemum Society (two days).

Friday, 11.—Nottingham Chrysanthemum Show. Leicester Chrysanthemum Show (two days).

Monday, 14.—National Chrysanthemum Society: Floral Committee.

Tuesday, 15.—Leeds Chrysanthemum Society (two days). Folkestone Chrysanthemum Society (two days). Winchester Chrysanthemum Society (two days).

Wednesday, 16.—York Chrysanthemum Society (three days). Hull Chrysanthemum Society (two days). Bristol Chrysanthemum Society (two days). Buxton Chrysanthemum Society (two days). Banbury Chrysanthemum Show (two days).

Thursday, 17.—Edinburgh Chrysanthemum Society (three days).

Friday, 18.—Stockport Chrysanthemum Society (two days).

Monday, 21.—National Chrysanthemum Society: Floral Committee.

Tuesday, 22.—Royal Horticultural Society: Committees meet.

Thursday, 24.—Dundee Chrysanthemum Society (three days).

Monday, 28.—National Chrysanthemum Society: General Committee.

DECEMBER.

Tuesday, 6.—Scottish Horticultural Association. National Chrysanthemum Society (three days).

Tuesday, 13.—Royal Horticultural Society: Committees meet.

Monday, 19.—National Chrysanthemum Society: General Committee.

OBITUARY.

MR. CHARLES GUNTHORPE, of the Old Fleece Inn, Buckingham, died, we regret to learn, at Westminster Hospital, succumbing to an operation for removal of a growth in the throat. He was seventy years of age, and, during the past half century, has been well known as a most successful cultivator of flowers and vegetables. His chief favourites were asters, verbenas, and French marigolds, the latter being generally wonderful developments. He was a large prize-winner in the amateur classes at Buckingham, Brackley, and Banbury shows, and formerly at Oxford.

A WONDERFUL INVENTION is one which, whilst being useful to the world, has never before been dreamt of by scientific men. Many astonishing proposals have frequently been made with reference to a revolution in our already rapid means of locomotion, but nothing practical has yet been effected. No doubt the time will come when a trip between London and New York will seem like a pleasant excursion of a few hours' duration. The ingenuity of man can accomplish wonders, and there is no telling when its limit will be reached. It will be difficult, however, to produce anything more wonderful than Holloway's Pills and Ointment. As sterling remedies for all complaints nothing can equal them.—[ADVT.]

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the Gardeners' Magazine. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forth coming exhibitions and meetings, and are requested to advise us concerning change of dates

Violas.—H. B., Timperley: There are about a hundred species of viola.

Potatos for Heavy Land.—A. F., Oxon: Six varieties suitable for heavy soils are Beauty of Hebron, Sirius, Up-to-date, Satisfaction, Early Puritan, and Windsor Castle.

Chrysanthemum Cultivation.—A. G., Manchester: We thank you for the suggestion, and will see what can be done in the matter. High quality blooms are as necessary for exhibition grouping as for staging, when cut, upon the boards; the general system of cultivation is the same in either case, except that those varieties which require such high cultivation to produce good blooms that they can only perfect one or two on a plant are not generally grown expressly for grouping. Extremely tall and leggy varieties are also omitted, except such as are amenable to the cut-back system. It is always advisable to grow a number of cut-back plants as well as a number of naturally dwarf varieties where plants for exhibition groups are required. We recommend a perusal of the series of articles on "Chrysanthemums for Exhibition" that appeared in the Gardeners' Magazine for 1896 and 1897.

The Spanish Silver Fir.—P. C., Blackheath: The Spanish Silver Fir, Abies Pinsapo or Picea Pinsapo, was introduced into England in 1839. It is a native of the middle and south of Spain, being plentiful on the Sierra Nevada at elevations of four to five thousand feet. It is characterised by its stout pointed leaves produced on whorled branchlets. It is a fine abies for lawn specimens, and is a suitable subject for cultivation on shallow soils over chalk. As it assumes a large size it should be placed so that eventually it may have a clear radius of twenty feet for itself. Abies Pinsapo variegata has yellow tips to leaves and branchlets, and these are most effective during the growing season. Another variety that does not come under general notice is A. Pinsapo Hammondi, a curious form with shortened stems and excessively developed prostrate branches that are clothed with branchlets and leaves, both smaller than in the type.

Mildew on Vines.—T. F. J., Norwich: As a stagnant atmosphere is the primary cause of mildew on vines or elsewhere it is obvious that the principal remedy will be a buoyant atmosphere, which can be very largely ensured by due care in heating and airing the varieties. Where mildew has been prevalent, as in your case, it is advisable to adopt other safeguards against renewed attacks. Perhaps the best plan is to paint the hot-water pipes with flowers of sulphur mixed with milk. Another is to place a few lumps of newly-slaked lime about the house, standing them in pans, and then strewing sulphur upon them; both these plans result in the giving off of slight sulphurous fumes that prove fatal to the mildew fungus. Sulphur must on no account be burned in the vinery, or both vines and mildew will be killed. Flowers of sulphur should always be kept in a dry place ready for use at any time; you should also obtain a distributor, so that should mildew show itself, the vines, leaves, and bunches may be dusted over at once. After such a dusting, say about four days after, it will be necessary to remove the sulphur by syringing with clean rain water.

To Kill Crickets.—W. S., Chelmsford: Although crickets are a great nuisance in some plant houses, and occasionally do considerable damage to some plants, we think you have rather overstated the case so far as their lease and tenacity of life is concerned. Obtain one pint of oatmeal, two ounces of arsenic, a little ground caraway seed, and some powdered aniseed; mix all together carefully, and lay small pieces on bits of broken glass, jam pots, or other glazed ware, and place about the house at night. As this is a deadly poison it must be carefully used, and any not eaten by the crickets should be taken up in the morning and locked somewhere out of the reach of children or domestic animals. Another mixture that may be used as an alternative, is to make a paste with arsenic and honey. If these poisonous preparations are placed on glazed ware they will be available, if not all eaten, for about three nights; after that they are too dry for the crickets to eat. A persistent use of these arsenical compounds for about a fortnight should effect a considerable diminution of, if not the entire clearance of, the plague. Subsequently it will be advisable to put down some poison every third or fourth week. We must again remind you of the need of caution, and for keeping children and domestic animals from the house when using the poison.

Ferns on Walls.—J. B., Dundee: One of the easiest methods of making what is generally known as a fern wall in a greenhouse or other structure is to obtain lengths of fairly stout wire trellis, but in comparatively small widths, and fix them from three to six inches from the wall. Between the trellis and the wall pack in a mixture of thoroughly good turfy peat and loam, facing this with moss next the trellis. Commencing at the bottom of the wall, and using strips of trellis about fifteen or eighteen inches wide, and as long as the extreme width of the wall to be covered, it will be easy to fill in the soil and moss and plant the ferns as the work proceeds. With wider strips of trellis it is difficult to fill in the soil firmly; the latter, however, is one of the chief points to observe, as there is bound to become shrinkage when water is supplied, but the less the better. Inch and a-half mesh will not be too small for the wirework. It will be necessary to use stout iron staples at intervals to keep the wire from bulging, and to distribute the weight of the whole mass. If a few light iron uprights can be placed at intervals, and the trellis wired to these, they will keep the work in position. Tiles can, of course, be used instead of wirework, and if these are preferred they can be obtained from any of the dealers in garden pottery who advertise in our columns. It will be necessary to specify your want and the area to be covered; you should also state whether you wish to hang or nail the tiles to the wall or cement them on to it.

Tree Fern.—W. S., Chelmsford: If the soil is at all sour it will be necessary to remove it and repot the specimen, using a lighter compost, and giving ample drainage. Syringe the trunk two or three times each day, making the spray as fine as possible, so that no great quantity of water runs down to the roots. The stems may be mossed, using fresh sphagnum, and then eventually its length may be reduced.

Names of Plants.—Under this heading we can only undertake to name species and specific varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp moss or leaves as packing material to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that the numbers be legible and firmly attached to the specimens. We cannot promise to name more than six specimens at one time from any one correspondent.

K. B., Henley: 1, the Winter Aconite (*Eranthis hyemalis*); 2, Pelargonium quercifolium minor; 3, not recognised, but probably a form of P. quercifolium; 4, P. denticulata majus; 5, P. radula major; 6, P. radula.

H. A., Rugby: The plant is unquestionably Camellia reticulata.

A. W. K., Yarmouth: Omphalodes verna.

Names of Fruits.—We are pleased to assist our readers as far as it is possible to do so in naming fruits, but it is absolutely necessary that they should send us good specimens carefully packed, as it is only when characteristic examples reach us in perfect condition that we are able to determine their names. We are compelled to insist on the observance of this rule, as so many specimens now reach us. We cannot undertake to name more than six varieties at one time; and both apples and pears should be sent when approaching maturity, but before they are fully ripe, that we may have the assistance of their distinctive colours in determining their identity.

W. A. S., Swanley: 1, Chatelay's Kernel; 2, Withington Fillbasket; 3, not recognised, probably a seedling from Cox's Pomona.

J. T., Putney: 1, Bedfordshire Foundling; 2, Frogmore Prolific; 3, Lamb Abbey Pearmain; 4, Roundway Magnum Bonum.

R. M., Colchester: King of the Pippins.

L. F. F., Carnarvon: 1, Round Winter Nonsuch; 2, French Crab; 3, Dutch Mignonne.

B. F., Leicester: 1, Catillac; 2, Easter Beurre; 3, Jean de Witte; 4, Winter Nelis.

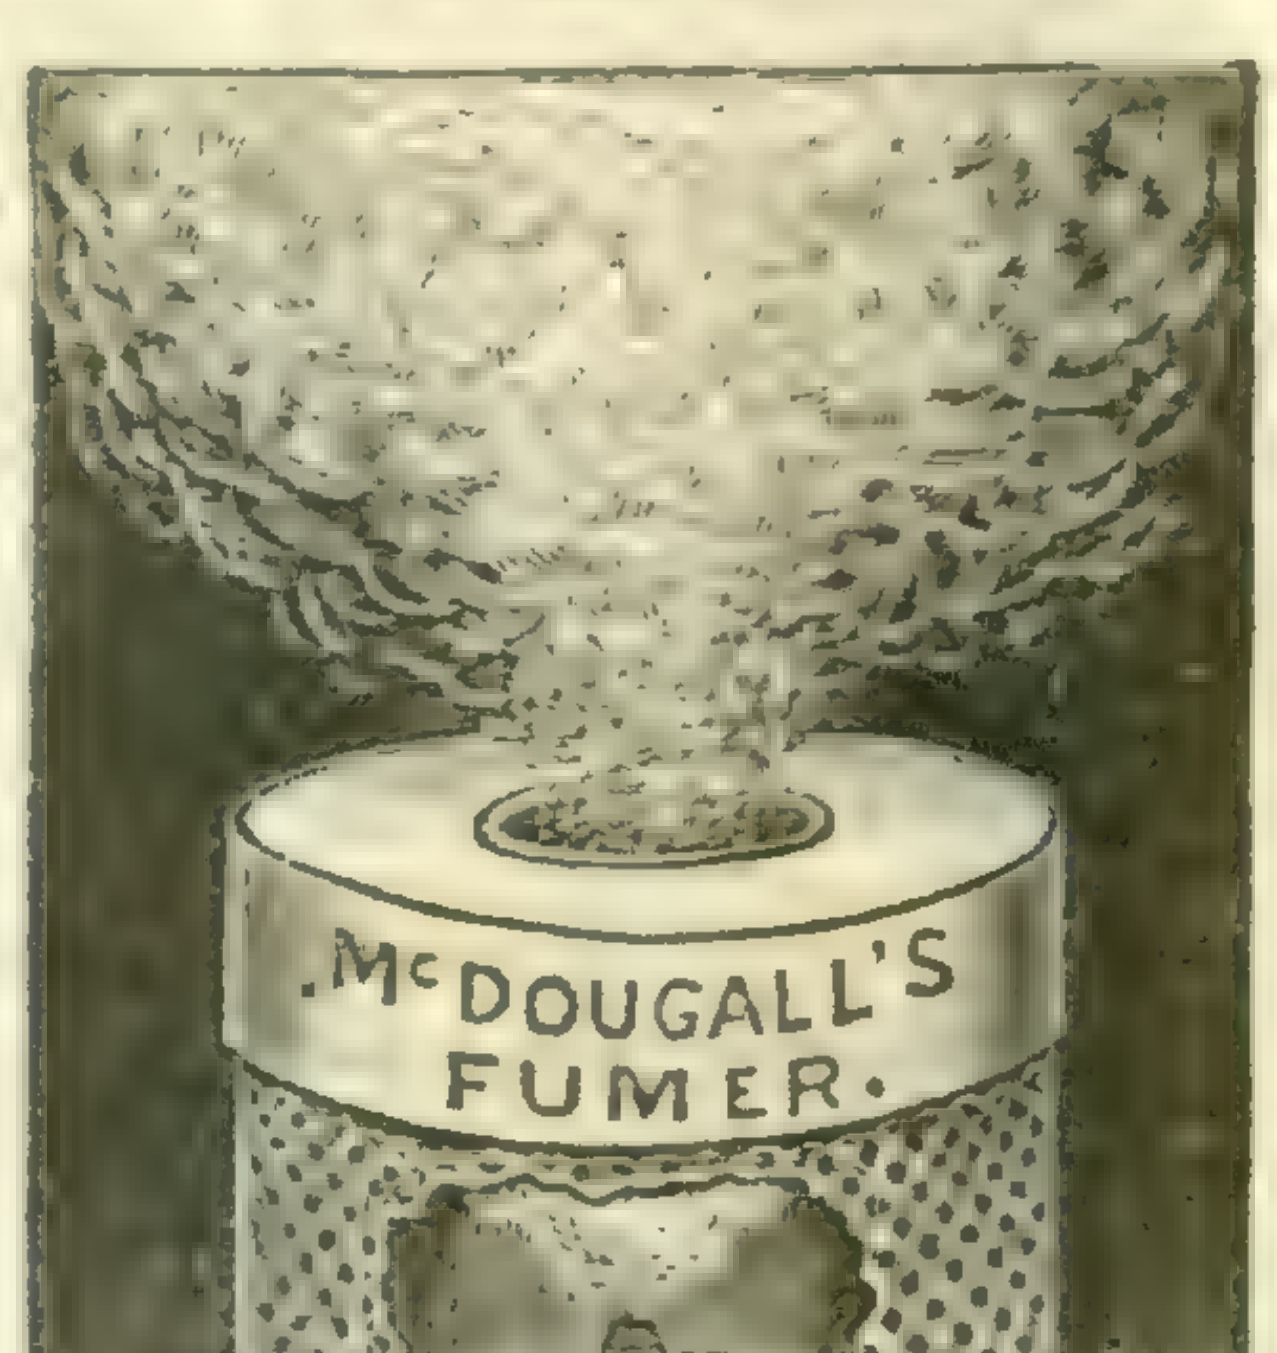
NEW INVENTIONS.

McDougall's Insecticide Fumer.—Much attention has of late years been devoted to the methods of fumigating plant and fruit houses with a view to their improvement, and as the result of the energy displayed, both in investigation and experiment, a considerable advance has been made both in simplicity and efficiency. The most recent of the inventions for the prevention and annihilation of plant pests is McDougall's Insecticide Fumer, introduced by Messrs. McDougall Brothers, 10, Mark Lane, and having the promise of proving of immense value. In their invention Messrs. McDougall have made a quite new departure in methods of plant fumigation, and devised a means whereby the pests that usually attack plants grown under glass can be destroyed in a remarkably simple and inexpensive manner. As shown in the accompanying illustration, the Fumer consists of a cylinder of perforated tin enclosing a small lamp, and surmounted by a reservoir containing the fumigating material. In using the invention the first point is to estimate the cubic contents of the house, and then distribute the requisite number of Fumers over the floor of the structure and place each one upon an inverted flower pot or a piece of brick. The next step is to prise off the little cap that covers the opening of the reservoir, then lift off the reservoir, light the wick of the lamp, and replace the reservoir in position. In a very short time the material will give off fumes sufficiently powerful to destroy the insect pests within their influence, but in no way injurious to the most tender vegetation. When the Fumers have been used they are gathered up and thrown on the rubbish heap, consequently there is no trouble in refilling or rewicking the lamps. We have subjected the Fumers to a careful trial, and have been much impressed with their simplicity of construction and efficiency in operation, and have formed a high opinion of their utility, more particularly in the gardens of amateurs, who have but little time to devote to the management of their plants.



CATALOGUES RECEIVED.

Pape and Bergmann, Quedlinburg, Germany.—Seeds.

R. Dean, Ranelagh Road, Ealing, W.—Hardy Plants and Seeds.

W. Fromow and Sons, Chiswick, W.—Seeds.

Wood and Ingram, Huntingdon.—Vegetable and Flower Seeds.

Cooper, Taber, and Co., Southwark Street, London.—Seed Catalogue for France and Germany.

John Sharpe and Son, Bardney, Lincoln.—Gardening Guide.

Wm. Cutbush and Son, Highgate, N., and Barnet, Herts.—Seeds and Chrysanthemums.

R. Sydenham, Tenby Street, Birmingham.—Seeds.

Michael Rains and Co., Mansell Street, Aldgate.—Seeds.

F. Gee, Biggleswade, Bedfordshire.—Seeds and Plants.

Benjamin Soddy, 243, Walworth Road, S.E.—Seeds.

Samuel Dobie and Son, Heathfield Gardens, Chester.—Seeds.

Fisher, Son, and Sibray (Ltd.), Handsworth, Sheffield.—Seeds and Sundries.

Dobbie and Co., Rothesay, N.B—Seed Catalogue and Competitors' Guide.

Cooper, Taber, and Co. (Ltd.), Southwark Street, S.E.—Wholesale Seeds.

John Green, Norfolk Nurseries, Dereham.—Seeds and Plants.

J. Cocker and Sons, Aberdeen.—Seeds and Plants.

J. Turner, Wetherby, Yorks.—Seeds, Chrysanthemums, and Dahlias.

Vilmorin, Andrieux, and Co., Quai de la Megisserie, Paris.—Seeds.

John Fraser, South Woodford, Essex.—Roses, Fruit Trees.

MARKETS.

Covent Garden.

THERE is a moderate supply of fruit on offer, but English apples and pears are conspicuous by their absence. Home-grown grapes. American and Canadian apples, and French pears meet a ready sale at fair prices. Vegetables in moderate supply; potato trade dull.

FRUIT.—American and Nova Scotian apples, 14s. to 35s. per barrel; English grapes, 1s. 6d. to 3s. per lb.; Almeria, 10s. to 22s. per barrel; bananas, 4s. to 10s. per bunch; pineapples, 2s. to 5s. each; French pears, 4s. to 6s. per case; Messina lemons, 6s. to 18s. per case; Valencia oranges, 12s. to 20s. per case; Jaffa, 8s. to 11s. per box.

FLOWERS.—Arums, 2s. 6d. to 4s.; carnations, 1s. to 3s.; eucharis, 3s. to 4s.; gardenias, 6s. to 9s.; Lilium Harrisi, 4s. to 6s.; tea roses, 6d. to 1s.; pink roses, 1s. to 3s.; cattleyas, 6s. to 9s.; Odontoglossum crispum, 1s. 6d. to 4s.; tulips, 6d. to 1s. 3d.; and tuberoses, 6d. to 9d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; chrysanthemums, 9s. to 18s.; marguerites, 2s. to 4s.; mignonette, 2s. to 4s.; pelargoniums (scarlet), 6s. to 8s.; white narciss, 2s. 6d. to 5s.; and violets, 9d. to 2s. per dozen bunches; azaleas, 6d. to 9d.; stephanotis, 4s. to 6s.; Roman hyacinths, 6d. to 9d.; lily of the valley, 6d. to 2s.; and pelargoniums, 6d. to 1s. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 3s. to 4s. per bunch.

VEGETABLES.—Canary tomato, 1s. to 1s. 6d. per tray; English onions, 4s. 6d. to 5s. 6d. per cwt.; Valencia, 6s. to 7s. per case; Brussels sprouts, 1s. 3d. to 1s. 6d. per half-sieve; French endive, 1s. 4d. to 1s. 8d.; lettuce, 1s. 3d. to 1s. 9d.; cauliflowers, 1s. to 2s. 6d.; cucumbers, 4s. to 7s. 6d. per dozen; celery, 6s. to 15s. per dozen rolls; seakale, 10s. to 15s. per dozen punnets; spinach, 2s. 6d. per bushel; forced rhubarb, 1s. 6d. to 2s. 6d. per dozen bundles; savoys and cabbages, 3s. to 5s.; parsnips, 2s. 6d. to 3s. 6d.; beetroots, 2s. to 3s. per tally; turnips, 3s. to 3s. 6d.; carrots, 2s. 6d. to 3s.; parsley, 2s. per dozen bunches; mushrooms, 6s. to 9s.; eschallots, 1s. 9d. to 2s. per 12 lb.

Borough Potato Market.

With fairly large supplies and a quiet trade prices are practically unaltered.

Dunbars, 115s. to 125s.; Hebrons, 90s. to 105s.; Snowdrops, 85s. to 95s.; Bruce, Maincrops, and Sutton's Regents, 85s. to 90s.; Reading Giants and Saxons, 85s. per ton; Belgians, 3s. 6d. to 4s.; Germans, 4s. to 4s. 6d. per bag.

ENGAGEMENTS FOR THE ENSUING WEEK.

The mean reading of the Barometer during the week at Greenwich was 30·37 inches, and that of the Thermometer 42°·4, the latter being 3°·4 above the week's average in the 50 years 1841—90. The direction of the wind was south-westerly, the horizontal movement of the air being 37 per cent. below the week's average in the 16 years 1860—75. The duration of registered bright sunshine in the week was 2·2 hours. No rain was measured during the week.

Also in thumbs at 8s. per 100. All good healthy stuff packed, and put on rail free for cash with Order.
HILL and Co., Wright's Nursery, Turner's Road, Lee, Kent.

GREEN PEAS—JUNE TO NOVEMBER.

A correspondence was raised in the Daily Press last Autumn upon the shortness of the season when Green Peas are available, both in gardens and on the market. We now offer the following as representing the best collection selected from 1,024 rows we had under trial last season. It would be difficult for us to give precise dates for putting the seed into the ground, as so much depends upon soil and situation. Successional Sowings may be made any time between these dates, and the last sowing not later than the second week in June.

SEED LIST

(Free on Application).

FEATURES.

Alphabetically arranged.
Best sorts, in heavy type, can be seen at a glance.
Probably the most explicit practical instructions for cultivation ever published.
Many hints and recipes for cooking and serving the various vegetables.
Directions for the storing and forcing of vegetables.
Medicinal qualities of many vegetables and herbs.
Prizes of £5, £3, two of £2, and £1 offered for Photographs of Horticultural Subjects (see page 2 of Catalogue).

THE LIST, containing 93 pages, and a profusion of illustrations, shows (A) **What to Grow**; (B) **How to Grow it**; and (C) **What to Do with it when Grown**; and has been described by an agent on one of the largest estates in England as a BOOK OF REFERENCE.

Another Customer, testifying as to quality, writes: "I should like to add that all the Seeds, &c., purchased from your establishment during the past 14 years have been of the very best quality, and have given great satisfaction."

COMPETITION DEFIED!
OUR UP-TO-DATE SEED CATALOGUE

for 1898 proves that our prices are far below any others. We guarantee our Seeds to be

NEW, GENUINE, and RELIABLE.

In dealing with us great benefit is derived, as we do not spend our clients' money in costly advertisements; nor is our Catalogue a work of art, entailing enormous expense (needless to ask who pays for this). We have shown what we can do in the BULB TRADE on the score of economy and excellence, and we shall supply our Seeds on the same basis. Therefore, send for our Catalogue (free), and judge for yourselves.

EPPS'S COCOA.

EXTRACT FROM A LECTURE ON "FOODS AND THEIR VALUES," BY DR. ANDREW WILSON, F.R.S.E., &c.—"If any motives—first, of due regard for health, and second, of getting full food-value for money expended—can be said to weigh with us in choosing our foods, then I say that Cocoa (Epps's being the most nutritious) should be made to replace tea and coffee without hesitation. Cocoa is a food; tea and coffee are not foods. This is the whole science of the matter in a nutshell, and he who runs may read the obvious moral of the story."

NATIVE GUANO.

BEST AND CHEAPEST MANURE FOR GARDEN USE.

Price **£3 10s.** per ton in bags. Lots under 10 cwt., **4s.** per cwt., 1 cwt. sample bag sent carriage paid to any station in England on receipt of P.O. for **5s.**

Extracts from 22nd annual collection of reports:—

NATIVE GUANO FOR POTATOS, VEGETABLES, &c.

C. H. TINDALL, Bardney: "Used for Potatos. Result very satisfactory; yield much above average. A splendid manure." G. WATTS and SONS, Bournemouth, report: "Good for general purposes. Grand for all Root Crops, Tomatos, and Cucumbers. Find it so cheap; and it does not exhaust the ground like other manures."

NATIVE GUANO FOR FRUIT, ROSES, TOMATOS, &c.

E. F. USHER, Sidcup: "Potatos and carrots, splendid crops; Peaches, Nectarines, &c., splendid. Should not like to be without it on any consideration." G. STONARD, Gardener to Sir A. T. Watson, Bart.: "Used for seven years for Peaches, Grapes, Tomatos, Cucumbers, Roses, and Chrysanthemums with excellent results."

Orders to the **Native Guano Co. (Limited)**, 29, New Bridge Street, Blackfriars, London, where pamphlets of testimonials, &c., may be obtained. Agents Wanted.

NOTES OF THE WEEK.

THE NATIONAL CHRYSANTHEMUM SOCIETY.

On the day with which the current month will be brought to a close the National Chrysanthemum Society will hold its annual meeting, and in view of recent events it appears to us desirable that those who are interested in the society should in the interval carefully consider its present position and any method which occurs to them as likely to improve it, for the purpose of submitting their views to the members. There are several rumours in the air with regard to propositions that will be brought forward on the occasion in question, and it is, therefore, desirable that the members who are able to do so should make a point of attending, and take such course with regard to the matters that arise as may appear likely to prove beneficial to the society. It would be well were the members from beyond the metropolitan boundary to assemble in larger numbers than is usually the case, for the purpose of taking part in the election of the members of the executive, and there can be no doubt that it would be an immense advantage were the members of committee to be drawn from a wider area. There is a great difficulty in selecting for election on the committee members who reside a considerable distance from London, for few so placed can afford the time and expense involved by a regular attendance at the meetings, and it has been found that when members resident in distant parts of the country have been elected they have attended so seldom as to have rendered but little service. We should be glad also to see on the committee a larger number of amateurs who combine with a love for the chrysanthemum business experience which is so essential in the management of floricultural societies as of other bodies, and this point should be borne in mind at the annual meetings and on other occasions when vacancies have to be filled. The election of the executive should be a sufficient reason for the attendance of members, and if any further inducement is required, it will this year be found in the fact that at the forthcoming meeting a new code of rules will be submitted to the members. As the preparation of the code has occupied a specially-appointed committee for several months, and has been adopted by the general committee, it may be assumed that the new rules will, if passed, greatly improve the methods of procedure. The burning question at the present time is the place of holding the exhibitions, and it would be greatly to their interest if the members would take advantage of the annual meeting for expressing their opinions upon the question, so that the views of the society as a whole may be ascertained. It would certainly be an advantage to the society were members of the executive who desire reforms to submit them to the committee, and, failing to gain their point, appeal to the members assembled in general meeting, and, as a matter of course, present some scheme on which a business-like discussion could be based. This is the practice adopted in other societies, and should be insisted upon by the members of the National Chrysanthemum Society, for in no other way will it be possible to have the assistance of horticulturists of position in the administration of affairs. The society has accomplished much useful work and has great possibilities ; but while we have no doubt that the committee will be able to show that much useful work has been accomplished during the past year, and that they have prepared a liberal programme for the coming season, we are strongly impressed with the necessity for care on the part of those responsible for the management of the society, more particularly in the direction of maintaining its prestige.

MAGNETISM IN FERN LIFE.

In the course of Professor Ray Lankester's second lecture on "The Condition of Life of the Simplest Living Things," a reference, as stated in our last issue, was made to a recent discovery by a German professor that the antherozoids or fertilising bodies in ferns, which form the homologues of the pollen grains in flowering plants, are attracted to the archegonium or egg-cell by the presence therein of malic acid, which had previously been found to attract them when applied to the prothallus independently of the situation of the ovary. It is, however, extremely doubtful whether there is anything akin to magnetic attraction in this phenomenon, and the phrase used "as if by a magnet" presumably only implies a resemblance in the effects rather than identity of cause. These antherozoids on emerging from the antheridia or sperm-cells swim about actively and freely in the moisture necessarily present on the under side of the prothallus ; and this they do by means of cilia or slender, hair-like processes, which serve the purpose of oars, and with the aid of these they make their way to the archegonium and fertilise the egg-cell situated at its base Clearly, given an organism gifted with means of locomotion, which implies a certain amount of volition, it is not going very far to consider it endowed with some perception of odour or flavour sufficient to determine its movements towards the source, precisely as we know that certain insects are attracted to their mates from long distances over which magnetism would be very unlikely to act. Besides, considering the extremely limited area of the prothallus, if magnetic force were the determining cause locomotory cilia would hardly be necessary, especially since both the antheridia and archegonia are immersed in water and an extremely weak attractive force would therefore determine the eventual connection. It has long been recognised by botanists as a biological fact that the pollen grain has been evolved from the antherozoid, and some Japanese botanists have recently found the missing link, as it were, in the fertilising bodies of the Gingko, or Maidenhair Tree (*Salisburia adiantifolia*) whose foliage of adiantum-like leaves shows the close affinity it has otherwise retained to its ancient progenitors. This being so, it would be interesting to know whether the bursting of the coat of the pollen grain and the subsequent direction of the tube it emits, could also be affected by malic acid independently of the stigmatic surface ; that is to say, whether—leaving the idea of magnetism out of the question—the pollen grain has inherited the instinct of its ciliated ancestors, and directs the course of its tube towards the far-distant ovary for similar reasons. If this were so, it is not beyond the bounds of possibility that malic acid might come in as an aid to fertilisation where crossing or hybridising were found to be hindered by the lack of a needed stimulus. Clearly, in such cases as these, we come closely into touch with those extremely subtle influences which lie altogether outside our human range of sense-perception ; but there is no doubt that a careful study of the effects will often enable us to infer the cause, and that being done to utilise our knowledge in fresh and profitable directions.

PLANTING FRUIT TREES.

So far, the autumn and winter has been pre-eminently favourable to planting, and there have been but few breaks in the continuity of the process. Nurserymen admit that the season is one of the most favourable they have experienced for years. It is not too late to plant, but it should be done quickly. In the case of some pears the flowering buds are already showing the colour of the calyces ; and the sheath which formed their protection during winter has parted obedient to the impulses of the spring time. Early autumn is undoubtedly the best time to plant, but there are times when circumstances delay the work, but if possible February should see it accomplished, weather permitting. When an old Lancashire gooseberry grower remarked that it was a good day's work to plant five gooseberry trees, he had in his mind the perfect and complete performance of the task. Despite all the teaching given in respect of this particular work, there is much fruit-tree planting done in a very perfunctory manner. A short time since we were invited to inspect some standard apples planted two years ago, and found to our dismay that a hole had been dug, the roots thrust into it, and filled in with soil of a decidedly unsuitable character. But little growth had taken place since the trees were planted, and the fruit one or two of them had produced was small and cracked. These trees had been sent from a respectable nursery, and were planted by an individual sent with them, who was supposed to be properly qualified for the task. And not only is bad planting done, but where trees are intelligently placed in the ground, they are yet placed too deep in the soil. The roots are too far away from the influence of the sun, and there is never such a healthy root action as when they are nearer the surface. In the case of heavy land imperfectly drained, it would be better to plant on the surface, after it has been broken up, pulverised and properly prepared. Such trees, and especially so if they are standards, should be staked at once, because there is a lack of proper anchorage until the roots have penetrated the soil and secured for the tree a firm foothold. Fruit trees planted at this late period of the winter should be well mulched, for though February is regarded as a wet month, March is frequently a dry one, and then surface mulching is highly advantageous. The mulching also serves the purpose of keeping frost from the roots ; and who knows what wintry weather may be in store for us ere Lady Day is past, and in this relation it may be well to suggest that there are many fruit trees, especially in old gardens, that do not bear fruit, or if they do, only unsatisfactory produce, because the roots are starved. Gardeners who highly manure their vegetable ground, do not appear in some cases to realise the fact that their fruit crops fail for lack of root sustenance. A little bone meal applied on the surface, after it has been carefully broken up, would work wonders ; especially if followed by a good mulch of manure. What may appropriately be termed surface culture, the encouragement of surface rooting, does not appear to be so much considered as it should. Even on a deep gravel subsoil, with a shallow layer of loam on the surface, very vigorous trees and fine crops of fruit may be secured by good mulchings and plentiful waterings, when necessary. A good gardener once said that he believed that at the present time there are plenty of trees in this country to produce fruit for all our requirements if properly cared for, and there is a great deal of truth in the remark.

IMPORTS OF FRUIT AND VEGETABLES.

Although not so satisfactory as those of the opening month of 1897, the Board of Trade returns for January last do not contain anything to justify more than the ordinary degree of anxiety with regard to the commerce of the United Kingdom. The imports show an increase in value of £140,823, equal to 0·3 per cent. ; but there was a decrease in the value of the exports of British and Irish produce of £554,832, equivalent to 2·8 per cent. Happily, there was an increase in the exports of foreign and colonial produce nearly equal to the decrease in home products. The imports in which we are specially interested show a considerable degree of irregularity, and also that we continue to be largely dependent upon the produce of foreign and colonial gardens and orchards for much that could be profitably grown at home. The imports of apples were again considerably in excess of those of the corresponding month of last year ; but there can be no doubt that the supplies were considerably short of the quantities we should have received had the American crop not been considerably below the average. The total quantities received during the month were 295,551 bushels, of the value of £98,972 ; or an increase in quantity of 14,560 bushels, and in value of £33,366. There was a drop of 380 bushels in the imports of grapes, and the values of these fruits was lower by £516 as compared with the imports in January, 1897, the quantities received being 1,001 bushels, of the value of £1,476. We had but three bushels of plums sent us last month against none in the corresponding month of last year, and 210 bushels in January, 1896 ; and it is interesting to observe that while the plums imported in the last-named month were returned as of the value of £820, or equal to nearly £4 per bushel, the value of the three bushels received last month is given as £1, or 6s. 8d. per bushel. The imports of pears were 3,060 bushels, of the value of £1,544, or an increase of upwards of 400 bushels. Nuts used as food that were received from abroad are returned as of the value of £24,383, and with regard to these it must be said that they consist chiefly of nuts that cannot be profitably grown in this country. Of unenumerated fruits the imports amounted to 56,441 bushels, of the value of £29,934 ; and for the greater proportion of these also we must continue to depend upon supplies from beyond the boundaries of the United Kingdom. The imports of potatos show an enormous increase as compared with January, 1897 and 1896. In the opening month of these two years our imports amounted to 23,465 cwt. and 41,672 cwt. respectively ; but last month the supplies jumped up to 739,955 cwt., of which 147,141 cwt. came from Germany, 122,023 cwt. from France, 1,061 cwt. from the Channel Islands, and 469,730 cwt. from countries not specified. Our bill for potatos received from abroad was necessarily a large one, and the total was £140,050. In the imports of onions there was a material drop, the quantities received being 443,749 bushels, or about 50,000 bushels less than in the corresponding month of last year, and upwards of 150,000 bushels in January, 1896. Unenumerated vegetables, on the other hand, have been sent us in largely increased quantities, and our bill for them is somewhat heavy.

Primula obconica Hybrids.—During the early spring months of 1897, Mr. C. E. Shea devoted a considerable share of his attention to the hybridisation of Primula obconica with P. sinensis, and it is with much satisfaction that we record the fact of his having been successful in obtaining crosses between these two distinct species. A small proportion only of the plants obtained from the crosses have yet flowered, and of these two have come under our notice which afford unquestionable evidence of hybrid origin. In one case the yellow belt surrounding the tube of the corolla of the Chinese primula has been transferred to the flowers of the hybrid, and in the other the flowers have the overlapping convolute lobes, characteristic of the flowers of the higher types of P. sinensis. In the second of the two hybrids there is evidence also of the influence of the last-named species in the calyx of the flowers. The seed-bearing parent was P. obconica, and so far there does not appear to have been any material change in the foliage or in the colour of the flowers, but now that a break has been obtained, changes in the form of leafage and the colour of the flowers will follow as a matter of course. Since writing the above, we have learnt that the Scientific Committee of the Royal Horticultural Society arrived after a close examination of the plants at the same conclusion as ourselves, and consider that a cross has been effected between the two species in question.

Mr. James H. Veitch has consented to preside at the smoking concert to be held at Anderton's Hotel, Fleet Street, on Monday, February 14. The concert is in aid of the funds of the National Chrysanthemum Society.

Botany and Allied Subjects are by no means overlooked by the Paris Academy of Sciences, as a reference to the recently-published list of prizes offered during 1898 and the succeeding three years will show. Those subjects and prizes of most interest to our readers are in botany : The Barbier prize of 2,000 francs for discoveries bearing upon the art of healing ; the Desmazières prize of 1,600 francs for the best study of cryptogams ; the Montagne prizes of 1,000 francs and 500 francs for memoirs bearing on the anatomy, physiology, and development of the lower cryptogams ; the De la Fons-Melicocq of 900 francs for botanical work on the North of France ; and the Thore prize of 200 francs to the author of the best work on the cellular cryptogams of Europe. In the department of physical geography there is the Gay prize of 2,500 francs for a comparison of the marine floras of the Bay of Biscay and the Mediterranean. In geology, the Vaillant prize of 4,000 francs is offered for a work relating to the microscopical study of sedimentary rocks, chiefly in connection with their origin and the modifications undergone since deposition.

Awards of R.H.S. Committees.—At the meeting of the Royal Horticultural Society on Tuesday the Council adopted a new mode of awarding the medals at the fortnightly meetings. Hitherto each committee has made awards to the collections coming within its province, but under the new arrangement a sub-committee of nine, consisting of three members of each committee, was appointed to determine the relative merits of groups. It is not surprising the change in the method of procedure should have given rise to much discussion, and we were pleased to have the assurance of Sir Trevor Lawrence at the annual meeting that he would recommend the Council to revert to the practice which has for some years past obtained in the case of the Floral Committee.

Club-root in Turnips.—The disease caused by the slime fungus known as Plasmodiophora brassicæ is not less destructive in Scotland than in England, and consequently the experiments that have been made on Lord Rosebery's estate, near Edinburgh, are of much interest to cultivators. In experimenting upon finger-and-toe in turnips, resort was made to the bold expedient, for the purpose of testing a certain course of treatment, of sowing turnips again upon land where the crop had been nearly destroyed by the disease in the preceding year. The dressing adopted was one ton of freshly-ground lime per acre immediately before ploughing in the autumn, one ton of ground lime in the spring, and eight cwt. of kainit per acre sown in the drills. So efficacious did this dressing prove that the crop grown under its influence was practically free from the disease. It was found, however, that the use of superphosphate, or of any other manure in the production of which sulphuric acid is employed, had a detrimental effect, and favoured rather than discouraged the development of finger-and-toe. Some experiments were also made with manures for turnips, and these proved very satisfactory. The land had received 35 tons of dung per acre, and grown a potato crop in 1895, followed by barley in 1896. The condition of the soil is shown by the circumstance that the plots unmanured in 1897 yielded 24 tons 8 cwt. of turnips per acre. The best result—31 tons 8 cwt. of dressed roots and three tons of shaws per acre—was obtained from a dressing of 4 cwt. of superphosphate, 6 cwt. of lime compost, and 1 cwt. of sulphate of ammonia, at a cost of 22s. per acre. The lime compost would contain about one-third of its weight of lime. The profit in using this mixture, as compared with the unmanured land, was £2 8s. per acre. Where sulphate of ammonia was replaced by its equivalent in nitrate of soda the yield of roots was less, whilst chemical analysis showed them to be somewhat inferior in quality.

Truffle Cultivation.—At a recent meeting of the French Academy of Sciences, Mons. Chatin referred at length to the researches made by many leading French scientists for the purpose of discovering the mode of propagation and some system of cultivation of truffles. He then submitted that Duc de Leparre had, he believed, discovered the secrets that had so long been hidden. The Duc considered that truffle spores were conveyed to the leaves of certain trees by insects, and here they germinated, and with the falling leaf came to the ground to fully develop their mycelium and complete the cycle, by fruiting or producing the edible truffle.

The Commons Preservation Society, meeting under the presidency of the Right. Hon. G. Shaw Lefevre, recently considered a report presented by its hon. solicitor, Mr. P. Birkett, upon the provisions of private Bills affecting commons, open spaces, rights of way, and roadside waste. It appeared that notice had been given of the proposed introduction of fifty-four private Bills under which powers are sought to acquire, in the aggregate, nearly 1,700 acres of common and other open land, and to extinguish a large number of rights of way in different parts of the country. It was determined to make further inquiries concerning a number of the Bills, and should the promoters be unwilling to agree to grant favourable terms to the public the society determined to oppose the Bills in Parliament. It was resolved to support in the High Courts an appeal with regard the ownership of a large tract of turf fuel allotments in Cornwall. It was decided to appeal to the public for further support.

Dean Hole stated at a recent meeting of the Worshipful Company of Fruiterers, that we are the most ignorant of any civilised nation in regard to the culture and treatment of vegetables. We certainly do not agree with the former part of the statement, but, as the Dean remarked, we are behind our neighbours the French in the matter of cooking the vegetables we have cultivated. Dean Hole concluded his remark with the story of a farmer who dined at a lord's table, and, on being asked to partake of some Jerusalem artichokes, exclaimed, "If I couldn't grow better 'taters than them I'd know reason why."

Fossil Fungi.—Mycologists and others interested in fungi will be glad hear that Dr. L. Meshcinelli, of Vicenza, proposes to issue during the next or two an Iconograph of All the Fossil Fungi known. The work will take form of a quarto volume, will contain an atlas of over thirty plates, and will be published at thirty francs (25s.)

Manure for Cabbage Crops.—Dr. Bernard Dyer has been and is stil conducting a series of experiments in Kent in connection with the Manuring of Market Garden Crops, and in some details given in the *Agricultural Gazette* one of the points raised is as to whether the common plan of manuring land to be planted with cabbages in the autumn is advantageous. The point can hardly be regarded as settled by the experience of the last two seasons; but, so far as that goes, it indicates that the result of feeding the plants early is to force them undesirably forward, only to be injured and to some extent killed during the winter. This experience is opposed to the common impression that farm or stable manure "keeps the plants warm" during severe weather, and helps to preserve them. Of course, any stimulating chemical manure would force the plants even more than farm or stable manure in the autumn; but phosphates can be applied before planting with advantage. The case of spring-planted cabbages is different, as the effect of any manure put on for them takes place during a period of growth not interrupted, as that of autumn-planted cabbages is, by a long spell of frost, when the winter is severe. But such extremely mild autumns as those of 1896 and 1897 are exceptional, and it is still a question whether, in an ordinary season, dunged cabbage crops are in any danger of becoming too forward before winter sets in regularly.

"The Botanical Magazine" for the current month contains a double-page illustration of Richardia Elliottiana, the finest of the richardias; this has a golden yellow spathe, and is a native of South Africa. A curious error has crept into the letterpress accompanying the illustration, for it is stated that the plant was raised from seed in 1896 and exhibited in London in 1892. Cypripedium Chamberlainianum is figured under the generic title of Paphiopelum; it is now a well-known orchid; Daphne Blagayana, a sweet-scented, white-flowered species known since 1837, but not long in cultivation; Dasystachys Drimiopsis, an African plant from the Zambesi valley, and with spikes of white flowers akin to the asphodel; and Anemone vernalis, with white and violet-purple flowers, a species closely allied to the British A. Pulsatilla, are all figured in the same issue.

The Röntgen Rays and Vegetable Life.—The results of the action of Röntgen rays upon vegetable life have hitherto been negative, but now, according to *Nature*, Signor G. Tolomei has been led to the conclusion that their action is identical with that of light. On exposing to the action of Röntgen rays branches of Elodea canadensis immersed in water charged with carbonic anhydride, evolution of bubbles took place as in the presence of sunshine or electric or magnesium light. The same similarity was observed in the effects on the lower vegetable forms, both Röntgen rays and light causing retardation in the absorption of oxygen by Mycoderma aceti, and in the evolution of carbonic anhydride by Saccharomyces. Again, in their action on Bacillus anthracis the Röntgen rays behave in the same way as sunshine, but in a minor degree; when a gelatine film was exposed for twenty-four hours to the radiations from a Crookes' tube, with the interposition of a zinc screen having an X-shaped aperture, the letter appeared transparent on an opaque background. That the action was due to destruction of the germs, and not to the generation of any toxic quality in the agar, was proved thus: When a sterilised film was partially exposed to the rays, and subsequently brought into contact with a stratum of dried spores the spores began to germinate all over the film; but when the stratum of spores was exposed to the rays, the screen with the letter X being interposed, and the film subsequently brought into contact with them, only those spores which had been protected from the Röntgen rays developed, and the letter X was distinctly seen. Signor Tolomei attributes the previous failure to obtain such effects to the short duration of the exposures.

The Gardeners' Company held a most pleasing function at the Royal Institute of Painters in Water Colours, Piccadilly, on the evening of Friday last. The Master, Mr. N. N. Sherwood, on this occasion gave a reception and entertainment to a large and fashionable company. Ladies were invited, and the proceedings were consequently among the most successful ever held in connection with the company. Mr. and Miss Sherwood received the guests, the latter carrying a splendid bouquet presented by the Livery, and wearing the handsome diamond brooch recently presented to her by the Court. Following the inspection of the collection of pictures now in the galleries, the company gathered in the East Gallery, where a varied programme of music, juggling, animated photographs, &c., was provided. Subsequently dancing took place in the Central Gallery, the music being discoursed by Ashton's band. Supper was served in the West Gallery from eleven to twelve o'clock, and altogether the company enjoyed themselves hugely.

The Board of Agriculture distributed the Parliamentary grant made in 1896-7 in aid of Agricultural Education in Great Britain as follows: Durham College of Science, Newcastle-on-Tyne, £1,000; University College of North Wales, Bangor, £800; Yorkshire College, Leeds, £800; University College of Wales, Aberystwith, £800; Reading University Extension College, £800; Nottingham University College, £600; Cambridge and Counties Agricultural Education Committee, £500; South-Eastern Agricultural College, Wye, £400; Eastern Counties Dairy Institute, Ipswich, £300; British Dairy Institute, Reading, £300; Bath and West and Southern Counties Society, £300; Royal Botanic Garden, Edinburgh, £150; Highland and Agricultural Society, £100; Agricultural Research Association, Aberdeen, £100. Fourteen institutions have thus shared the total amount of £6,950, and the Board has, in addition, undertaken to inspect the agricultural work done under the instruction of these bodies, and also that of seven county councils.

Dr. D. Morris, C.M.G., will deliver at an early date two Canton Lectures before the Society of Arts upon the interesting subject of india-rubber.

Water under Regent's Park.—The Zoological Society have, at their Regent's Park Gardens, long wished for an independent water supply, and, after some experiments, this has now been secured by the boring of an artesian well. Pure water is now secured from the chalk, and the boring of four hundred and fifty feet now yields 240,000 gallons per day.

NEW PLANTS, FLOWERS, AND FRUITS.

ANTHURIUM DR. LAWRENCE.

A BOLD and handsome anthurium, with large foliage and salmon-pink spathes. The latter measure eight inches by seven and a half inches, so that they are most effective, especially when staged in tall vases with a few of their deep green sagittate leaves. A large specimen plant of this variety would always prove attractive in a stove, whether in flower or not. The spadix is large, pale pink, with a yellowish apex. F.C.C. Mr. Bain, gardener to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking.

CALANTHE SPLENDENS.

An exceptionally fine calanthe, with rich rosy-red flowers shaded with crimson. The parentage was not recorded. The sepals and petals are whole, of a rich rosy-red colour, while the lip has the addition of a distinct crimson or cherry red shade down the centre. Five flowers were on the small plant staged. A.M., R.H.S., February 8. Mr. Norman Cookson, Oakwood, Wylam-on-Tyne.

PHAIO-CALANTHE GRANDE.

A very pretty and interesting hybrid, with creamy sepals and petals of moderate size, streaked with rose-red, lip large and broad, sides lightly turned up, deep red with a crimson throat, and a few mottlings of creamy white. This is a hybrid, produced between Calanthe Bryan and Phaius grandifolius; the foliage of the latter has been much reduced. A.M., R.H.S., February 8. Mr. Norman Cookson, Wylam-on-Tyne.

APPLE LORD HINDLIP.

This is a fine late dessert apple of conical shape. The colour is dark yellow with scarlet shading and crimson markings. Eye small and closed, set in rather a shallow and plaited basin. The thick short stalk is deeply inserted. Two years ago this variety gained an award of merit, and on that occasion we considered it a valuable apple and figured it in the GARDENERS' MAGAZINE of February 29, 1896. We reproduce the illustration so as to call our readers' attention once again to first-rate a fruit that has now gained the highest award. F.C.C., R.H.S., February 8. Mr. J. Watkins, Pomona Farm, Hereford.

APPLE LORD HINDLIP.

LÆLIA ANCEPS WADDONIENSIS.

A splendid form of L. anceps, and very distinct. It has very large and substantial flowers, with white sepals and petals, and a large white labellum that has a broad and thick golden crest and a few lines of pale purple on the side lobes. The fully-developed flowers measure four and a quarter inches across, and four inches from the tip of the dorsal sepal to the apex of the lip. Two spikes, each carrying two flowers, were shown on the plant staged. F.C.C., R.H.S., February 8. Mr. Harris, gardener to Philip Crowley, Esq., Waddon House, Croydon.

CUCUMBER EVERY DAY.

This is a medium-sized variety producing even fruits that have scarcely any tail. They are deep green and indeed very handsome and useful. The specimens shown were cut from plants that have been fruiting since August, 1897. A.M., R.H.S., February 8. Mr. Owen Thomas, gardener to Her Majesty the Queen, Windsor.

PEAR PASSE CRASSANNE.

A splendid late pear. Obovate in shape; brownish russet over a deep yellow ground colour. Size rather large, segments stiff and erect, set in a deep depression surrounded by several ridges, stalk three-quarters of an inch long. Flesh melting, though slightly gritty towards the centre, very pleasant and rich. F.C.C., R.H.S., February 8. Mr. S. Woodward, Barham Court Gardens, Maidstone.

LATHYRUS SPLENDENS.

A handsome species with long growths and racemes of seven to ten intense crimson flowers. This is a native of Southern California, and was discovered in the San Bernardino Valley by Mr. Pringle in 1872. Seeds sent to Kew in 1894 germinated, and a specimen planted in a house devoted to Cape bulbs flowered for the first time in 1897. It is not hardy at Kew, succumbing to the winter cold, though growing freely out of doors during summer. *Bot. Mag.* 7,575.

ENGLISH AND ITALIAN GARDENS.

Of the many interesting and attractive exhibitions held in the galleries of the Fine Art Society, New Bond Street, none appeal more directly to those who find one of their chief pleasures in horticultural pursuits than do the exhibitions of water-colour drawings from the pencil of Mr. George E. Elgood, R.I., and it would be difficult to conceive anything more successful than they invariably are. A few years since Mr. Elgood covered the walls of these galleries exclusively with drawings of English gardens, in which he depicted with exceptional success the varied aspects of the flower garden of the present day, and gave us many glimpses of old gardens in which are still remaining examples of the yew-clipped hedges and statue-furnished alcoves so dear to the hearts of our forefathers, when formality was regarded as one of the more important attributes of the English flower garden. That exhibition afforded abundant pleasure and entertainment to those who were fortunate enough to have an opportunity of leisurely inspecting and enjoying the pictures, and it must have been of great educational value by reason of the many suggestions it afforded for enhancing the attractions of the flower garden. It would appear to have exercised a considerable influence upon public taste, so far as it relates to the ornamental aspects of the art of gardening, for in several gardens that have come under our notice during the past few years we have had evidence of a desire on the part of the owners to repeat some of the formal features which Mr. Elgood so admirably pourtrayed, and Addison, Pope, and other of the advocates of the natural system so strongly condemned. Mr. Elgood, it must be stated, does not appear as an advocate of formal gardening; and if he has depicted some of the more important of the examples of the formal style, it has been because of their strong appeal to his artistic perception, as in the case of the many examples he has given us of the more natural style which at the present time is held in the highest estimation. Strong as is our affection for the English or natural style of garden, we are not prepared to so freely condemn the advocates of some formality and of closely clipped hedges, for there can be no question that the latter when judiciously placed are of immense value for the shelter they afford to plants coming from warmer climes than our own, and also for the protection they give to those who appreciate the manifold attractions of the garden, but from advanced age or some other cause suffer more or less from exposure to the cold winds usually experienced during the spring months. In this exhibition, now rapidly drawing to a close, we have scenes in countries other than our own, and of the eighty drawings the majority have as their subjects gardens on the shores of the Mediterranean, within range of the smoke-capped peaks of Etna and Vesuvius and other parts of Italy.

In justification of the course he has taken in selecting as subjects for his pencil gardens under the Italian sky, Mr. Elgood directs attention to the fact that it is in Italy rather than in France that we must seek for the origin of the earliest use of statuary in the flower garden, and for much of the formality that characterised the English garden from two to three centuries ago. That this is so we have ample evidence. We know that at the beginning of the sixteenth century there was a great revival in the art of gardening in Italy, and that the most famous gardens at that period were those of Lorenzo de Medici and the wealthy Bernard Rucelli. Both these gardens were geometrical and architectural, and, while reflecting the gardening taste that prevailed in the time of Pliny, they served as models for other great Italian gardens for some two hundred and fifty years—in fact, until there was a reaction from severe formality and a more natural style introduced. A great impetus was given to a revival of the use of statuary in gardens quite early in the sixteenth century by Cardinal d'Else, who, in forming the garden of his villa erected on that of the Emperor Adrian near Rome, found a number of antique sculptures and distributed them over the grounds. This mode of garden ornamentation was subsequently imitated by Francis I. of France, and was afterwards adopted in other European countries. As a further proof of the formality which characterised the Italian gardens three centuries ago, it may be mentioned that at the beginning of the seventeenth a poem was published at Milan under the title of "L'Adamo," and that the illustrations, which are intended to represent Paradise, are full of closely-clipped hedges, square flower gardens, straight walks, uniformly-topped trees, regular knots, and marble fountains. The gardens attached to the villas in and near Rome were also more or less formal, with architectural groves and devices cut in box and other plants, and it is reasonable to assume that Le Notre, who exercised so great an influence upon garden design in France during the seventeenth century, obtained some of his ideas from the gardens of Italy. Mr. Elgood, in the course of his rambles in the last-named country, found many charming scenes as subjects for his pencil, but some of those depicted convey the impression that the gardens are remnants of the past; and, notwithstanding the charm of a considerable number, we search in vain for the wondrous beauty found in the more important of the examples of English gardens.

Remarkably pleasing is the drawing of "Lilies: Amalfi" (No. 1), the broad belt of the Madonna lily which skirts the pergola of the old monastery, now the lounge of an hotel, presenting a charming effect in contrast with the blue water within the range of vision. Not far removed is the garden of "A Villa at Palmero" (No. 7), in which a marble fountain is the most prominent, and contiguous to it is a rockery, formed with stones evidently obtained from some ruins near at hand. The "Villa Cadenabbio, Lake of Como" (No. 16) is more remarkable for the superb view obtained of the famous lake than for its gardenesque features, but the arch over which one of the robust-growing tea roses is running riot and producing a profusion of flowers, is singularly effective, with the grey mountain as a background. "Villa Pallombo" (No. 19) and "Villa Rosazzo" (No. 23) convey an excellent idea of the old-time gardens, the first containing broad, straight walks with clipped yews, and the second is distinguished by its bold stonework and geometric beds of flowers. By the "Olive and Vine at Florence" (No. 39) we obtain a pleasing glimpse of some of the characteristic scenery of Italy, and are reminded of Mrs. Browning's lines, which we should imagine were written with some such scene as is here depicted fresh in her mind:—

> "From the outer wall
> Of the garden, drops the mystic floating grey
> Of olive trees (with interruptions, green
> From maize and vine) until 'tis caught and torn
> Upon the abrupt line of cypresses
> Which signs the way to Florence."

"Under the Pepper Trees at Palmero" (No. 20) represents a charming garden with beds of roses, and in "Villa Giulia at Palmero" (No. 63) we obtain through an archway a delightful peep of an old-time garden. Clipped hedges with flowers peeping over them are prominent in the drawing of "Villa Armentani: Le Cava" (No. 30); in the "Boboli Gardens, Florence" (No. 31) we have an admirable object lesson in the use of annuals, and in the "Pergola San Lazzaro" (No. 32) day lilies are well represented. "The Padua Botanic Gardens" (No. 45) is interesting for its grey fountain and the numerous busts with which it is surrounded, and "The Monastery Gardens, Momeale" (No. 47) is remarkable for its clipped hedges and masses of poppies; whilst "Poppies Villa, Palmero" (No. 49) reminds us of some of our more attractive English gardens; and "Lac Bourget, Aix-les-Bains" (No. 64) affords an excellent example of the tasteful grouping of flowering plants in conjunction with standard roses.

Attractive as are the greater proportion of the Italian gardens depicted in Mr. Elgood's drawings, it is with a considerable degree of pleasure that we turn from them to the representation of English gardens, for it is in these we find the charms that so greatly help to justify the belief that in no part of the world can we find gardens to surpass those of the United Kingdom. We might linger long over this section of the exhibition did time and space permit, but the pressure upon both are too great to admit of more than a brief reference to the more important. The gardens of the old timbered Manor House of Tangley afford a wide range for selection of subjects for the brush and pencil of the artist, and it is not surprising that Mr. Elgood should have taken advantage of some of the many opportunities they afford for the display of his artistic skill. "Tangley Manor House" is the subject of No. 29, and its open timber work, mullioned windows, and grey thatch lend themselves readily to artistic treatment; and embosomed in trees just commencing to assume their autumnal tints, with closely-cropped hedges, and a slow-flowing canal, it presents a highly picturesque appearance. Tangley Manor may be described as

> "A brave old house! a garden full of bees,
> Large dropping poppies, and Queen hollyhocks
> With butterflies for crowns."

"Michaelmas Daisies: Tangley (No. 3)" admirably demonstrates the value of the perennial asters for giving colour to the flower garden in the autumn. The plants are grouped together at one end of a broad sloping border, and the great masses of blue, white, and purple, present against the background of shrubs a delightful effect, and indicate the manner in which these elegant autumnal flowers can be employed to advantage. "Forecourt at Great Tangley" (No. 21), represents a charming scene, the walls nearly covered with the slender growth of the grape vine taking on its autumn tints and the beds filled with bold masses of heleniums, Japanese anemones, and roses. "The Pergola at Tangley" (No. 25), is remarkable for the bold masses of Michaelmas daisies, Japanese anemones, rudbeckias and Pyrethrum uliginosum, and these present a striking and pleasant contrast to the pillars of yew. In "Friendship's Garden" (No. 13), Mr. Elgood has given us an excellent example of the garden which Lady Warwick has recently described, and the scene, if one that does not from a decorative aspect specially commend itself, is of much interest. We have a red-brick house surrounded by a lawn, on which are comparatively small beds occupied by Michaelmas daisies, helianthus, and Japanese anemones, and lavender, the last-named consisting of large bushes of goodly age. "The Garden of the Sundial" (No. 40), represents another aspect of the gardens at Easton, where a clipped yew gnomon and dwarf box numerals form a greensward dial, with the appropriate motto, "Les heures heureuses ne comptent pas," and of this we may say with Marvell:

> "How well the skilful gardener shew,
> Of herbs and flowers this dial new!
> Where from above the milder sun,
> Does through the fragrant zodiac run."

Some of the glories of Hardwick are depicted in "The Yew Walk" (No. 12), a long walk with yew hedges, in which at intervals are statue-furnished alcoves, and "The Forecourt" (No. 59), in which flowers and the time-stained masonry [illegible] in happy combination.

The gardens of Newland Manor have afforded some delightful studies of roses. In "The Rose Garden: Newlands" (No. 50), and "June Roses: Newlands" (59), we have two of the most beautiful pictures in the exhibition. In the first-named the arches covered with roses and clematis are exceptionally good, and the beds of bush and standard roses somewhat irregularly arranged on a fine breadth of turf at once arrest attention by reason of their vigour of growth and profusion of flowering. In the second of the two drawings we have a broad walk flanked on either side with bush and standard roses, and spanned at intervals with arches of roses, the popular W. A. Richardson being conspicuous. Very fine also in the borders are the finely-developed specimens of white campanulas and lilies, and other hardy plants in which the gardens of Newlands Manor are particularly rich. The two drawings of most interest to rosarians are perhaps, "A Corner of the Deanery Garden: Rochester" (No. 17) and "The Dean's Garden: Rochester" (No. 65), which may be described as two of Mr. Elgood's most successful efforts. They show that if the president of the National Rose Society no longer aspires to the honours of the exhibition, that his love for the rose is in no way diminished. In the first of the two pictures we have a border of bush and standard roses, and in the second huge flower-laden bushes vie with splendidly-developed specimens of the more beautiful herbaceous plants in converting into a wilderness of flowers the broad borders that skirt the principal walk leading to the deanery, of which a delightful peep is obtained. There are many other drawings to which we should like to refer, but sufficient has been said to indicate the interest of the exhibition and the artistic merit displayed in the drawings of Italian and English gardens.

Market Grapes.—A few days since I looked in at the grape-growing establishment Mr. Bennett has at Cobham, Surrey. It is a place that gives much pleasure even at this time of the year, when nearly all the vines are resting and but one or two houses have been started; because in every direction the vines looked so well, were kept so close spurred, and so neat. Every [illegible] gets a coating of a solution of caustic soda and commercial potash, [illegible] warm with the aid of a paint brush, and that painting serves to keep [illegible] thoroughly clean. Glass, paint, and floors, too, are thoroughly clean. The [illegible] in some houses had recently been lightly forked over and received a dressing [illegible] manure. Mr. Smith, who is Mr. Bennet's able cultivator, prefers to [illegible] chemical manures in a raw state and do his own mixing. After the dressing [illegible] applied a thorough soaking of water is given to the soil, and then the [illegible] well prepared for the work so soon to be required of them. In one house [illegible] being prepared for planting, old soil had been excavated and partially re[illegible] and was being replaced by such fresh soil, chiefly roadside trimmings, as [illegible] obtained. That was mixed with some of the old soil, and crushed bone and [illegible] dust was being intermixed. The coarse manure of bygone days did not enter [illegible] market vine culture. But I was most impressed with the sight of six new [illegible] hundred and fifty feet, spans twenty-five feet wide, erected side by side with [illegible] party walls. Each house was planted with one hundred Gros Colmar vines, [illegible] total of six hundred of this one famous market variety. This is, it is true, [illegible] small accession to the great number of vineries being constantly erected in [illegible] directions; but all the same, however, it helps to illustrate the exceeding growth [illegible] the grape-producing industry, in spite of the fact that in their season grapes [illegible] very cheap. That it is possible to get a capital return from cheap grapes when crop and quality are commensurate, is one of the certainties of to-day.—A. D.

SOME HARDY TERRESTRIAL ORCHIDS.

HAVING made many attempts to cultivate in the open border the finer species of terrestrial orchids, including such kinds as the North American Habenaria fimbriata and H. psychodes, I have reluctantly come to the conclusion that the climate and surroundings of my garden at Edge can satisfy very few of them. Amongst those few, however, some are so ornamental as quite to make up for any attention they require, and where successful they become a special feature in the garden. First may be mentioned cypripediums, of which C. calceolus claims our sympathy as a persecuted member of indigenous natives of Britain, where it has been collected to extermination; but imported plants are easily obtained in nurseries. It requires stiff clay mixed with lime in some soluble form; lumps of limestone are of very little use for supplying this, as it takes years for them to dissolve sufficiently to impregnate the soil. It is a common fallacy to think that the requirements of lime-loving plants may be satisfied by planting them on a rocky compost of limestone, and, conversely, to think that because a plant thrives on a rockery of limestone, it cannot be a hater of lime. However, C. calceolus likes both lime and stone, and must have perfect drainage and an eastern aspect, not exposed too much to the sun. A deep projecting pouch surrounded with stone on the upper shelf of a rockery suits its taste. A top-dressing in winter of loam and rotten manure, with a little lime, pleases it, and when once established it may go on flourishing and increasing for a dozen years. Still, it is a capricious plant, sometimes disappearing unaccountably, and requiring to be renewed.

The North American cypripediums are different in their requirements, liking a deep peaty soil, but still exposed to the east, and mixed with abundance of good sweet leaf-mould. The finest is C. spectabile. I have not found this do well if planted, as imported, in large sods containing half-a-dozen or more crowns; it is better to separate the crowns and to shorten the roots of each to about two inches long. Then they should be planted three or four inches deep in a place where they will never get dry. If not planted too far apart they will soon grow into a compact mass, and by giving a rich dressing every year of rotten manure and leaf-mould, they will be encouraged to grow two feet or more high, bearing in June two flowers on each stalk. The same treatment suits C. pubescens and C. parviflorum; though if they had the perfect rest of a colder winter, and the stimulus and ripening of a hotter summer, I believe they would thrive better than they do in the climate of Cheshire. The only other North American cypripedium I have grown in any quantity is C. candidum, which has a small white flower, scented like a violet. Some twelve years ago I received from my son, then living in Minnesota, a hamper containing a dozen fine clumps of this species, besides a good many of the three other kinds described. All had been found growing together in a glen running north and south, and whilst common on the side facing the east, not one was on the side facing the west. Under the treatment described for C. spectabile, C. candidum seemed to do well, and flowered healthily for two or three seasons, but the plants gradually deteriorated, and not one of them remained alive seven years after they were planted.

Next to cypripedium the genus orchis produces the handsomest hardy species which can be grown with success in my garden. The largest flowers are borne by O. foliosa, known as the Madeira Orchis, and though a native of that mild climate, it is quite hardy in English gardens—that is, I have never known it killed by frost in winter; but hard frosts and east winds cripple and stunt the growth in spring, and in situations where it is exposed to these unfavourable conditions late in the season, it dwindles away. But in a sheltered border, sloping towards the east, in rich loam, mixed with well-rotted manure, it thrives and increases fast. The clumps may be separated and replanted at once, whilst the leaves are still green, about August, and they take no notice of their move. Planted in pots, not less than nine inches in diameter, and wintered in a cold frame, it will flower in the greenhouse at the end of May, and be secure against the dangers of an English spring out of doors. A native orchis, nearly related to the last, is O. latifolia, so extremely variable both in colour and robustness of habit that some botanists divide it into three or more species, but in some parts of North Wales, especially in the Anglesea bogs, they all grow together, and every gradation between them may be found. The richest in colour, as rich as new port wine, I found, I believe, in Conway marsh; these do not make a large spike, but retain their colour in cultivation. O. maculata, the commonest of our native orchises, likes stiffer soil than the others; I have found it do well in any flower border of strong soil; and, indeed, all the soil here is so full of the seed of this species that they come up in most unexpected places; no spot seems to be liked better than between the surface-growing rhizomes of the German iris. Giant forms of this species retain their size when transferred to the garden, and as they increase fast, clumps often produce a good effect.

There is no doubt that O. latifolia and O. maculata, where they grow wild together, readily cross, and the crosses, as a rule, are more robust than either parent. A very fine form, which has been known in cultivation for thirty years or more, and bears the name of O. maculata superba, or the Kilmarnock Orchis, is probably one of these hybrids. With the same treatment as that advised for O. foliosa, it is even handsomer than that species, and increases as fast, but I have never found it to succeed as a pot plant. But whatever the origin of the Kilmarnock Orchis, I have many orchises growing in my garden which I feel no doubt are spontaneous hybrids between O. maculata and O. foliosa. Having never grown orchises from seed, I cannot say how many years it takes for one of these terrestrial tubers to reach flowering size. Like lilies, they often show themselves, or at least are first noticed by me, when already ripe for flowering. It is more than ten years since I observed amongst a neglected clump of Orchis foliosa one or two with well-marked black spots on the leaves; these produced longer spikes but smaller flowers than O. foliosa—in fact, intermediate between the suggested parents. Since that time many more have appeared in different parts of the garden, some with spotted, others with plain leaves. The increase of these is even faster than that of the parents, and they make very good border ornaments. I think it was at the June show of 1896 of the Royal Horticultural exhibition, in the Drill Hall, that Mr. Pritchard, of Christchurch, had a fine bunch of these hybrids of O. foliosa of a better colour than any of mine. He had not recognised them as hybrids, nor had he sold any, but considered them a superior strain of O. foliosa. I believe that if any patient gardener would undertake the artificial crossing of these orchises, very good results might be obtained, especially by using a fine variety of O. maculata as one of the parents.

Edge Hall, Malpas. C. WOLLEY DOD.

P.S.—One important point in cultivation has been omitted. All the orchises described above are improved by having chopped sphagnum, mixed with the soil in which they grow, which is thus kept constantly and uniformly moist. I have proved by experiment that in the case of O. latifolia and of O. foliosa especially the greater vigour of plants so treated is very marked.

PROTECTING APRICOTS.

THE apricot, being naturally precocious, is one of the first of our hardy cultivated fruits to unfold its blossoms, and is therefore liable to extensive injury from frost unless adequate protection is afforded. The period at which flowering takes place depends in a certain measure upon locality, and to a great extent upon the character of the weather experienced in the early part of the year. The apricot being a native of warmer climes than ours the trees are quickly excited into growth. Therefore, should a spell of mild weather occur after the turn of the year the flower buds at once begin to swell, and they become quite prominent by the end of January. When this happens, the trees are then as a rule, in full bloom either by the middle, or not later than the end of February, generally speaking, the first-mentioned period. On the other hand, should January prove a cold month, and frost prevail to a greater or lesser extent, the flowering period is then delayed until March. In some seasons this occurs the second or third week in the month, and I have known it to be quite the end, and on a few occasions the beginning of April before all the blossoms have expanded.

According to present appearances the trees are likely to flower about the end of the month this season, although the buds are not so prominent as I have known them sometimes at the end of January. The last few days they have swelled up rapidly under the influence of bright sunshine, but a change has now set in, the wind having shifted from south-west to north-west, and cold showers of rain with some sleet with it keep passing over. This will give the trees a check should such weather continue, and the blossoming will be retarded to a later period than that mentioned. However, I am having preparations made for affording the trees protection in case the change to colder weather should prove but fleeting. When the buds arrive at the stage they are now in, my experience is that they will not withstand the effects of very severe frost, and I have known them killed outright from this cause. To prevent this occurring it is always a wise precaution to have something in readiness, so that protection can be afforded at short notice should a severe and protracted frost appear imminent. What this should consist of will depend on circumstances, or the means at command for acquiring the necessary materials. Blinds made of frigi domo, Hessian tiffany, and other materials offered by horticultural sundriesmen are all excellent, and by their means the trees are readily and effectively protected from inclement weather. These are, however, within the reach of but few gardeners, especially where rigid economy is practised, which unfortunately is too often the case at the present time. The majority have, therefore, to adopt more rough and ready modes. The next, which is perhaps the most extensively adopted, method of giving protection, is by means of fish-nets suspended in front of the trees. These may be doubled, trebled, or folded four times, according to their strength and the width of the mesh. Boughs of evergreens tied on hurdles also answer the same purpose, and these possess the advantage of being portable, and can be removed during the day. These evergreens may also be tied on stakes fixed some eight or nine inches from the face of the wall if hurdles are not procurable. The evergreens in this case should not be too freely used, otherwise the buds would be rendered very tender; all that is wanted being something to ward off frost and to break the cold winds. Laurels, yew, and spruce boughs are all serviceable for this purpose.

Another means of protecting the trees, which is also a great aid towards securing a good set, are copings. These not only shed the water clear of the trees during wet weather, but they are also convenient for screwing pulleys to, in connection with the raising and lowering of the blinds, as well as for fixing poles to, for keeping the latter and fish-netting from blowing against and damaging the buds and blossoms. These copings may consist of deal boards eleven inches wide by one inch thick. They are quite as effective as the more expensive glazed copings, and with ordinary care will last a number of years. These copings must be securely fixed under the wall copings, which latter seldom project more than two or three inches, so that they will remain immovable during the prevalence of rough winds during March. Irons somewhat like those used for supporting shelves in greenhouses, with chisel points for driving into the wall, are excellent for this purpose. The irons should be bent in a sloping direction, so that water will readily run off the boards, and a hole should be drilled near the outer end for the purpose of securing the boards with a screw. Stakes are, of course, easily procured in woodland districts, but where they cannot be had laths or battens, such as are used by slaters and tilers for roofing purposes, form good substitutes, and are moreover very cheap.

The foregoing are a few ways and means which may be adopted for affording the necessary amount of protection; but whatever is done, it is well to be prepared, so that when occasion requires the trees may be promptly shielded from harm. A. WARD.

POTATOS IN IRELAND.

THE current season has too fully borne ample proof to our shortsightedness in placing absolute reliance on the "noble tuber" for the staple food of this country. In many instances the supply is already exhausted, and in the cases of people out of employment it will be impossible for them to purchase potatos, as those are being sold wholesale in our local market at sevenpence to eightpence per stone of fourteen pounds which in other seasons would not realise twopence per stone. In the majority of cases where the crop was an average one the tubers are of such a bad quality as to almost render them unfit for human food. On boggy or moory land, also on strong, tenacious soils, the crop is exceptionally bad every way. The best result has been obtained on sandy or gravelly soils, and in such cases the crop is in many instances a very good one, while the cooking qualities are in every way excellent. Our own soil is sandy, and we had a very good crop; in fact, the best we have ever had. The ground is comparatively new, having been cultivated only four years, previous to which it was grazed for upwards of forty years. With the view to ascertaining if any more trustworthy variety could be grown than the Champion for the general crop, I, as intimated last spring, grew some thirty varieties, and propose now to give you the result of these trials.

First on the list is the old Cottager's Red, a variety seldom grown, as far as my observations go. This is every year a first-rate cooker, and of good cropping quality. Early Puritan came next, with an enormous crop of tubers, which, when cooked, were like balls of flour; I should pronounce this variety the very best that cottagers could grow for the earliest supply. An unusual occurrence last season with Myatt's Ashleaf and Old Ashleaf was, that the tubers, though plentiful, were miserably small, and of wretched quality when cooked. Both of these varieties can generally be relied on in gardens, but my experience of them as a field crop has not been particularly encouraging. Sutton's Ringleader, under similar culture, produced a very fine crop of tubers, but unfortunately the produce was of indifferent quality. Imperator produced a very fine crop everwhere, though those grown in the field were somewhat inferior, but those that were grown in the garden were all that could be desired. I hear some complaints of this variety as being too sweet in flavour. That popular variety in this locality with cottagers, viz., Flounder, I grew this year for the first time, and cannot too strongly condemn it; it was the first diseased, and that badly; it is a very poor cropper, and of wretched cooking qualities. Dreadnought, a variety sent me a few years ago by Messrs. Daniels Bros., had a very fine crop; but what was to me a new experience is that they are bad in quality when cooked. Another variety sent out by the Norwich firm is Remarkable, which produced the heaviest crop of enormous potatos I have yet seen; they must also take first rank for cooking quality. The Daniels, from the same source, as its name denotes, has always proved a decided success in the gardens, and in the field this year it produced a very fine crop, but of poor quality when cooked. Universal and Table King, two more kinds sent me by the Messrs. Daniels, prove two sterling varieties in every way, and I can strongly recommend them both.

Sharpe's Victor produced an excellent crop of potatos of first rate quality. Beauty of Bute is an excellent cropping variety of second-rate cooking quality. Main Crop I saw last year in county Kildare, producing an enormous crop of the finest potatos I ever tasted, they were grown on clay soil over lime stone; on the strength of their fine condition there I grew it this year with but very poor success, the tubers being small and of inferior quality when cooked. I regret to have to chronicle a similar report of King of the Russets. When I purchased seed of this variety last spring its rough skin excited my admiration and expectation to the highest pitch, but, alas, I was doomed to disappointment. Dunbar Regent produced an enormous crop of potatos of second-rate cooking qualities. The Bruce has generally proved a reliable variety in the past; last year, however, the tubers were small but plentiful, while their quality when cooked was far below the average. Sutton's Triumph, usually an excellent table potato, produced an excellent crop, but indifferent in quality. Holborn Abundance produced an enormous crop, but they were badly diseased; generally this variety is of poor quality here, a reputation I felt sure it would maintain in '97, but to my surprise the good tubers have proved as dry and as floury as possible. Village Blacksmith produced a very fine crop, but every year this is the worst variety of all to take the disease in its worst form. As a table potato though its quality is unequalled. Reading Ruby is another excellent potato, a very heavy cropper, but so susceptible to disease as to render it almost useless here in bad seasons. Carter's Goldfinder I grew this year for the first time; also Snowball from the same firm; both of these have produced a good crop of average-sized tubers, the quality in each case when cooked being very satisfactory. A round red seedling which I have been nursing for some years has quite disheartened me, and if it does not improve in quality next year, as it is an enormous cropper, I must only recommend its culture for pig feeding. Grampian, a round red potato that I received from Scotland, is in every way a splendid variety, and worthy of extensive culture here. The Sutton Flourball is another novelty with me; it is a round red variety, and was of all the sorts I grew the heaviest cropper; its quality when cooked was above the average. I shall, however, give all the varieties mentioned another trial during the coming season, as I do not consider the past wet season any reliable criterion.

About an acre and a half of the good old Champion were grown, and these produced an excellent crop of tubers of excellent quality. Some of the seed was from Kilkee, co. Clare, and the tubers from these were the smallest, and of the three lots of Champions grown were the worst in cooking quality. The produce of the Champions that we have been growing for the past eight years was very good in every way; but unquestionably the best results were obtained from Champions imported direct from Forfarshire last spring. The produce from these left nothing to be desired, and I believe it would pay anyone to import at least a portion of the required stock of potatos for planting direct fr England or Scotland every year—a system I, at any rate, intend to a The extra cost is very slight, and is amply returned the first year by the heavier crop. Very good results may be obtained by procuring potatos locally for planting that have been grown on a bog, if the ground to be planted is either sandy or limestone, or *vice versâ*, but not to be compared to imported seed. As will be noticed, I am compelled still to make the Champion our sheet anchor, failing another variety equally reliable.

Glenstal Farm, Limerick. R. WELLER.

BUSH-GROWN CHRYSANTHEMUMS.

PLANTS which are grown in bush form, that is, with a dozen or more shoots, to produce a quantity of small or moderately-sized flowers, are extremely useful for conservatory decoration; and, also, in giving a large supply of flowers for the many purposes for which cut flowers are required where the large blooms as grown for exhibition are not so serviceable. Highly-developed blooms give a striking and beautiful effect when rightly employed, not only on the plants or in exhibitions, but also as cut blooms in large vases, therefore I do not wish to suggest by any means that they are not of decorative value. The best rule to observe when arranging such flowers, as, in fact, in all floral work, is, that each bloom must stand clear of the others, so that any semblance of crowding is clearly avoided. With a judicious mixture of autumn-tinted leaves or other suitable foliage, and the blooms standing out boldly from the vase, large blooms of chrysanthemums are most pleasing.

The smaller flowers, however, lend themselves to many uses where large ones would be out of place, and it is incumbent upon all who have to provide quantities of winter flowers to grow these bush plants of chrysanthemums. The time when they are, perhaps, most useful is during December and January, and there are several very good varieties which bloom well to the end of the year, and a few which continue in good condition even into February. Those who grow a collection of border varieties will thus have good chrysanthemums from early September onwards for five months, and they are always useful. The single-flowered sorts are particularly desirable grown in this way, and well repay considerable attention. They also are well adapted for growing in six-inch pots from late spring cuttings. Besides these and the Japanese varieties there are one or two very pretty sorts with deeply-cut or tasselled florets, of which Mrs. Filkins is one of the best; and also the pompon varieties which deserve to be more extensively grown. A nicely-arranged basket of the charming little white pompon, Snowdrop, was awarded a first prize at the Royal Aquarium last November.

Especial qualities in the varieties grown for small flowers are g colours, particularly in white, crimson, yellow, and bronze shades; dwarf habit of growth and stout stems, which support the flowers well and with good foliage; then also freedom in flowering and in growth. A selection for growing in pots, that will carry on a succession of flowers, in the order of the names given, from the middle of October, are, of Japanese: Lady Fitzwygram, Wm. Holmes, Lady Selborne, Wm. Robinson, H. Shoesmith, Source d'Or, Mrs. Filkins, Tokio, Niveus, Golden Dart, W. H. Lincoln, Golden Gem, L. Canning, Princess Blanche; and of singles Kate Williams, Gold Star, Mayblossom, Purity, Framfield Beauty, Mary Anderson, Fanny Agate, and Mrs. D. B. Crane are well worth growing. Those named are all good, and though many more might be mentioned for November and December flowering, I think a limited selection is likely to be most useful. Of the late ones Golden Gem, Princess Blanche, and L. Canning are all in good condition with us now (January 31). It is impossible to speak too highly of Golden Gem, as it comes in so well at Christmas, and is a good keeper. It seems most necessary to make an effort to grow those which bloom at this late period in larger quantities, because of the limited choice in variety of flowers for cutting, and their extreme usefulness at this time, especially where flowers have to be sent a distance. Chrysanthemums pack so well and do not suffer from cold in transit, as many flowers do at this time of the year.

It is no advantage to strike cuttings later than January of these naturally late varieties. They require a full season's growth, and should not be pinched later than the second week in June. It is most important, too, that the growths should be well matured; and though liberal feeding is required through the summer months, this should be reduced during September somewhat to avoid a grossness in the shoots which are not likely to ripen. When the buds are well formed the feeding may be resumed. Mildew is a frequent cause of failure, more or less. The plants are often placed too closely together, and owing to the number of growths each plant carries, air and sunshine are not able to do their part in perfecting the growth, and hence the mildew soon works mischief by destroying the leaves, during September especially. Otherwise the cultivation of chrysanthemums as bush plants is extremely simple, though they fully deserve every care.

Trent Park Gardens. W. H. LE

Pear Jean de Witte.—This excellent pear is in season from J March, and is really one of the very best late-keeping dessert varieties; in I do not know its superior at this season. Though the fruits are not larg amples may be grown to a good size. The bright clear skin, covered with s of russet, changes to pale yellow ere the fruits are ripe, and thus makes it quite a attractive dessert fruit. The tree succeeds well on the quince stock, and is a abundant bearer. Like all late pears it develops its best quality when grown o a warm wall, and the crop should be allowed to hang on the trees as late i autumn as possible. I have no experience of this variety grown as standard o bush trained trees, but Dr. Hogg, in his "Fruit Manual," says, "The tree is vigorous and healthy, and an excellent bearer as a standard" Perhaps some of your can give us their experience of trees grown in the open. The variety was mended to me some years ago by Mr. Turton, of Maiden Erleigh, and a samples was convincing proof of its superiority and usefulness as a late W. H. LEES, *Trent Park Gardens.*

VEGETABLES FOR EXHIBITION.

Maize or Indian Corn.

MAIZE (*Zea Mays*) is generally cultivated in this country as an ornamental plant, and a splendid show it makes during summer and early autumn, when suitably used as a sub-tropical bedding plant. But it is none the less valuable when cultivated in the kitchen garden as a vegetable. It makes an agreeable change, and it is not nearly so extensively grown in this way as it deserves to be. A sheltered sunny spot should be chosen, which should be thoroughly manured and trenched during winter, leaving the surface as rough as possible till the spring. The seed should be sown about April 15, thinly, in boxes, in heat, and be made quite secure against mice, or they will quickly disappear. The young plants are very tender, so that care must be taken to properly harden them off in cold frames before planting out; planting should be done towards the end of May. The ground should be pricked over and made fine, after which plant in rows three feet apart, and eighteen inches from plant to plant. Abundance of water must be given at the roots during dry weather, and frequent hoeing to promote quick growth. A sowing may also be made the last week in April. The seed should be planted with a dibber and buried three inches. It is advisable to plant just about as thick again as it is intended to grow them, thinning out when large enough to the proper distance. Some of this sowing may also be transplanted if required, but the practice of sowing under glass is much to be preferred. The cobs of corn should be gathered when fresh and green, and when well grown it is surprising what a large quantity a small piece of ground will produce.

For exhibition in a decorative collection of vegetables maize forms one of the most striking features, and is most interesting to the visitors, while little preparation is required. The cobs of corn should be fully grown but not ripened. The outside skin should be opened down with a knife, and should be turned round to fully expose the corn, the beard, of course, being left on. About three dozen cobs will make a good dish, and they are best arranged on a layer of bright green moss and finished off with parsley. There are now many excellent varieties of maize in cultivation. The variegated kinds are most ornamental, but the variety I prefer for productiveness is Sutton's Early Dwarf Sugar Corn. The Japanese Striped is very ornamental, and where room can be afforded a small quantity should be grown; the variety Z. M. gracillimum variegatum is also good, perhaps the most graceful and ornamental of all, but very tender though less productive.

Mustard.

The culture of mustard (*Sinapas alba*) is of the most simple character, for, as a rule, mustard, with cress, forms one of the principal crops in our children's gardens. Being so quick to germinate, it is an ideal seed for children to sow, as they can almost see it grow after the first twenty-four hours, and in a few days the crop is ready for the table. One can well remember cultivating mustard as a child, and the joy experienced in cutting it for the tea-table. Mustard is much in request all through the year, and it is surprising what quantities are cultivated for our large markets, and the ready sale it obtains. Through the spring, summer, and early autumn it is easily grown in the open when hand-lights can be had, for here the growth will be quicker, and the quality consequently better. In spring and autumn the seed should be sown in warm sheltered positions once a week, but during the hot days of summer a cool shady spot is best. The ground should be broken up finely, levelled down, and the seed scattered moderately thick, but it should never be covered with soil, as it then comes free from grit, but be pressed down firmly with a piece of board. It should receive a good watering, and be netted or protected in some way from the ravages of birds. During the winter months it should be grown under glass in shallow boxes. In the early stages it will stand a very strong heat, and it can even be started on the hot-water pipes, but it must be finished in a cooler temperature, or it will often damp off and be worthless. There are two kinds in cultivation, the brown and white, but the latter is by far the best.

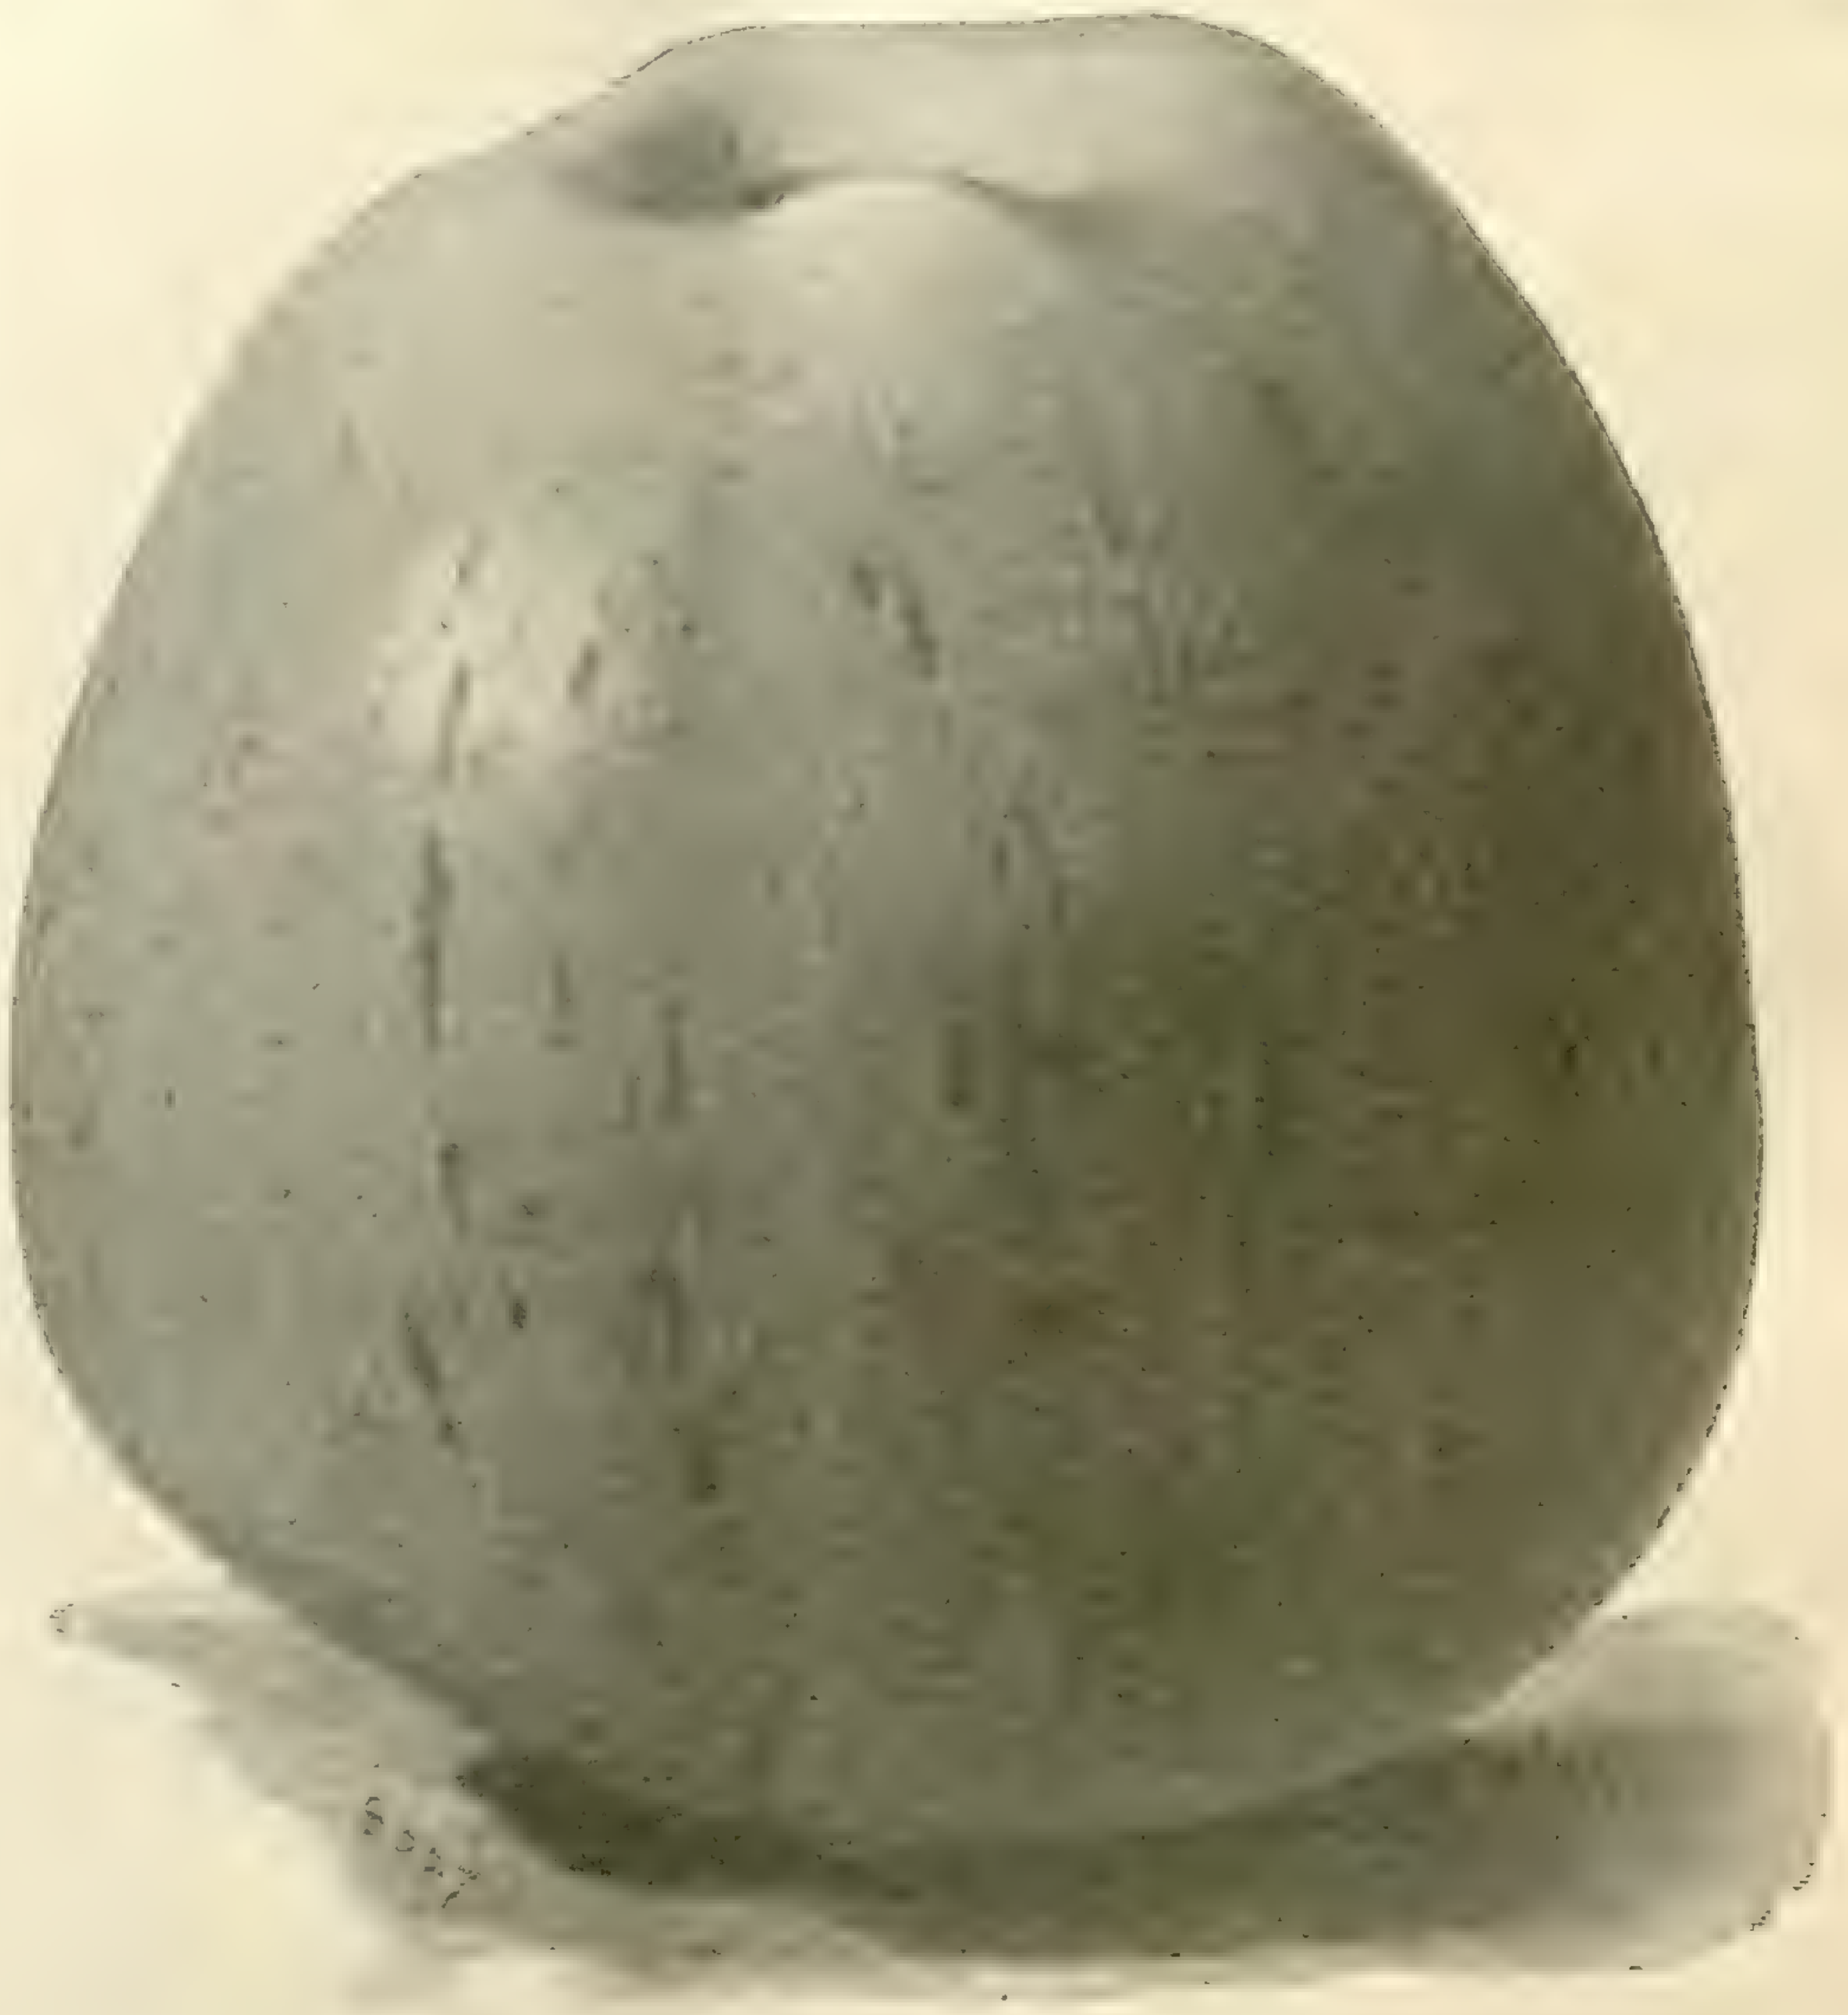
For exhibition, in a collection of salad or a miscellaneous collection of vegetables, mustard should always be included. For this purpose it should be grown and staged in punnets, either round or square. It should be fresh, of a good colour, and in length about one and a half inches, and show no signs of the second leaf. Well soak the punnets before staging, so as to prevent flagging.

Aldenham House Gardens. E. BECKETT.

Animal Manures.—As Mr. Willis refers at page 52 to these manures, though very briefly, I would like to ask of him some pronouncement of the relative values of ordinary stable or straw manure, and moss litter manure. This question is frequently asked, as also was the other day one as to the reason why moss-litter manure was esteemed useless for making of hot beds. Now the reasons I have given so far in reference to the two respective manures that an equal quantity of moss-litter manure is most fertile, as first: that the litter is itself of an active vegetable nature which soon decomposes, and then can be early utilised as plant food; and second: that because as a rule it lies longer under the horses, before removal, that it contains a greater proportion of droppings, and certainly a much larger proportion of urine than the straw litter does. Of course, straw, unless it be particularly decomposed by semi-fermentation, such as is furnished when manure is prepared for hot or mushroom beds, is much longer in being converted into plant food than is so soft a material as moss litter. My own impression is that to have ordinary straw stable manure is the very best form for soil dressing, it should be prepared just as it is the rule to prepare it for hot beds, keeping it from rains, allowing it to partially heat, but hardly to ferment. Keeping it frequently turned, and permitting no waste of ammonia. When so prepared, the long straw being removed and the droppings being furnished in greater proportion, it is as well preserved as can be and comes then much nearer to moss litter than it has before, except that it does not contain so much of urine, which is after all the most valuable manurial element.—A. D.

APPLE GOODWOOD PIPPIN.

HANDSOME apples of high quality that can be had in perfection during the first three months of the year are so extremely useful both for home and market supplies that it is desirable varieties in which these qualities are combined should be widely known; hence, in the interest of our readers, we give a characteristic illustration of the fine late apple to be henceforth known Goodwood Pippin. Fruits of the variety were first exhibited before the Fruit Committee of the Royal Horticultural Society on March 10, 1896, under the name of Lincolnshire Reinette. The specimens attracted much attention on that occasion, and were so highly appreciated by the committee that an award of merit for general good qualities and as a late-keeping variety was unanimously made in its favour. No trace having been found of an apple bearing the name of Lincolnshire Reinette, and as it was quite distinct from other known varieties, and the tree, now of great age, found at Goodwood, the exhibitor, Mr. Richard Parker, decided to name it Goodwood Pippin. The fruit is above medium size, roundish, inclining to conical, even and handsome in outline; the skin golden-yellow, brilliant crimson on the side next the sun, marked with patches of deep crimson; the flesh yellowish, rich, juicy, and firm. The variety is equally suitable for cooking and dessert, the fruits, when tastefully arranged, presenting an attractive appearance on the table. The tree is evidently a heavy and sure bearer, for it has borne an excellent crop in each of the four years Mr. Parker has been in charge of the Goodwood gardens.



APPLE GOODWOOD PIPPIN.

Cyclamen Pests.—Thrips are one of the most troublesome of pests with which the grower has to deal. Ordinary fumigating will not affect them, and whilst even the patent X L Fumigator will destroy aphis rapidly—indeed for that purpose nothing can be better—thrips are untouched. That is the testimony of that able market grower of cyclamen, Mr. May, of Twickenham. His practice, so soon as thrips are in evidence, is to make up a dipping solution of half a pint of fir-tree oil dissolved in two gallons of water, and then to gently immerse the plants, pot, and leaves into the solution. Not only are the insect pests then destroyed, but the plants seem to like the dip, as they brighten up and become stronger for the bath. There are many gardeners, perhaps, who may like to read of this method of getting rid of thrips.—A. D.

Poplars Destroyed by the Hornet Clearwing Moth.—In May 1897 the advice of the zoologist of the Royal Agricultural Society was asked with regard to young poplars, two of which had fallen, snapped off abruptly a few inches above the ground-level. Inspection of the fallen trunks showed the wood to be perfectly sound except in the region of the fracture, where some boring insect had evidently been at work. The standing trees were then examined, and every one was found to have the main roots and the bottom of the trunk extensively bored and excavated. From the borings a large number of pupæ and some dead larvæ were extracted, and identified as those of the Hornet Clearwing, (*Sesia apiformis*) of the poplar. Most of the specimens were dead, and the attack seemed practically at an end, but the trunks were so perforated at the base, and so rotted by the admission of rain to the burrows, that they were quite unfitted to withstand a moderate gale of wind, and the whole row would doubtless have succumbed in a very short time. As many as possible of the insects were removed, and an insecticide was injected into the borings by means of a syringe with an indiarubber tube attached. A small mound of stiff clay was then formed round the base of each tree to keep out the weather. The trees most severely injured were supported by stays. None have since fallen, and it is hoped that in time they will recover strength. The interest of the attack lies in the fact that Sesia apiformis is a comparatively rare insect, and that the injury wrought by it is generally trifling. There is no known record of its having caused the destruction of poplar trees.

DIPLADENIA BREARLEYANA.

THE dipladenias are among the most showy and interesting of stove climbers, and yet they are now rarely met with, and I think the reason is that modern cultivators do not succeed with them as well as with many other subjects. There are a number of kinds in cultivation, but I think the best of them all is D. Brearleyana, a garden hybrid, and one that flowers most freely when well grown.

The present month is a good time to start with a plant, which can be obtained from any nursery where stove plants are grown for a small sum. Not only does this dipladenia look well festooned under the roof, but grown in a pot for exhibition it has very few rivals. We have a specimen here that does exceedingly well; it is planted out in a square brick tank, eighteen inches long by the same in width. The soil it is planted in is composed of two parts fibrous peat, one of loam, and one of leaf soil, with some one-inch pieces of charcoal, plenty of sharp sand, and some dry half-inch bones. It is very important to have the latter very dry, otherwise they will ferment when in the soil and cause injury. After planting give it a thorough watering with tepid water, but little will be required until the plant has become well established, and then it must be given in very limited quantities, for dipladenias in general are very impatient of water, while D. Brearleyana is especially so. I find it does much better kept drier than most plants, and this is the secret of success in its cultivation.

When the young growths commence to start they will require something to climb up, until they reach the permanent wires on the roof; they like plenty of syringing, both in the mornings and afternoons on bright sunny days. Shut up the house while there is plenty of sun heat, and if the thermometer registers to 90 degrees, no harm will be done provided there is plenty of moisture in the house, D. Brearleyana revels in the sunshine, and especially when making new growth. When in bloom, however, it is desirable to give a little shade in the hottest part of the day, as the blooms then last much longer. Flowering commences about July and continues until October. After the latter month water should be entirely withheld for a couple of months at least, to enable the plants to receive a thorough rest, but the temperature should not fall below 55 degrees at night, remembering that dipladenias are natives of the Brazils, Trinidad, &c.

D. boliviensis requires a little more heat in winter than D. Brearleyana, and 60 to 65 degrees at night will not be too much for this lovely white species; it makes a good companion to the pink and purple forms, such as the new reintroduction, D. atro-purpurea. I had the pleasure of flowering the latter for the first time last year; it is evergreen, and a valuable addition to the stove climbers.

Totley Hall Gardens, Sheffield. T. W. BIRKINSHAW.

CANADIAN APPLES.

THE uneven packing, and general poor quality of imported apples, to which you drew attention in the issue of January 29, should give the necessary opportunity to British fruit growers to put good samples on the market, and so to regain some of the prestige for home-grown fruit which has been to a great extent lost. Now is the time, if ever, to restore confidence between buyer and seller, and every effort should be made to that end by selling only good samples which will compare favourably with the imported rubbish which has flooded the markets this year. It is much easier to lose prestige than to regain it, and there is no concealing the fact that imported fruits have met in the past with great favour among the middlemen, more from a matter of convenience than from anything in the way of superior quality. I have been enabled during this winter to inspect a great number of barrels and cases sent to local shopkeepers, &c., and have been astonished at the large quantities of poor fruits, and the bruised state they were in on arrival, especially as we hear so much about the admirable way in which they are packed, and how well they travel. These apples were supplied, wholesale, at prices which home growers rarely see for better fruits, viz., from 33s. to 22s. per nine stone cask; New York Pippins, in cases holding nine dozen fruits, are quoted at 11s. 6d. per case; Easter Beurre Pears, in cases holding forty fruits, at 18s. 6d. per case, and so on. When the cost of carriage and the shopkeeper's profit is added, the fruits only reach the consumer at a big price. In the same town first-rate samples of King of Pippins, and even of Ribston Pippins, have been selling at from 4s. to 6s. per bushel, these representing top prices; but I quite believe that it would not be so if confidence could be restored, and the shopkeepers could be brought to see that they can obtain supplies equal to the samples submitted for their approval; this they are at present very slow to believe, on the principle of "once bit twice shy."

Turning for a moment to the recent recommendation of "non-returnable" cases for packing. Would their use lead to better prices being obtained by the growers? It may be very well for growers on a large scale to adopt the system, but I do not see how it will benefit the small growers. At present empty boxes, &c., are sent very cheaply over rail from the central market, and being purchased wholesale they cost very little; but the small growers in the country could not obtain them at the same rate, and would still have the carriage to pay for, unless they could get them made at home, which would probably be more expensive still, through having to employ men not experienced in the work of light box making.

J. C. TALLACK.

A New Poinsettia.—M. Fatzer, director of the Forceries de l'Aisne, recently exhibited a new poinsettia in Paris. This, says *La Semaine Horticole*, is the result of a cross between P. pulcherrima and P. rosea. It has very brilliant bracts, which are produced fifteen days in advance of those of P. pulcherrima.

LATHYRUS SPLENDENS.

THE genus Lathyrus contains about a hundred and fifty species, almost all of which are both handsome and interesting plants. Their distribution is very wide, and only about ten species come from Western America. These latter, however, contain the gem of the genus, L. splendens, a species figured in the present issue. Mr. Pringle discovered L. splendens in 1882, in the San Bernardino Valley, Southern California. It is not, however, confined to this valley, but is fairly plentiful in the highlands of the southern part of the state, where it is known as the Pride of California. The first plants raised in Europe were obtained at Kew from seeds sent by Professor Green, of Washington, in 1894. One of these was planted out in a low span-roofed house in the private part of the gardens known as the Melon Yard. Here it produced a large number of stems, some being ten feet long; the growth is angular and sparingly branched. The foliage varies somewhat, but as a rule the leaves are two to four inches long, shortly petioled, composed of eight or ten opposite, alternate leaflets that may vary from elliptic to linear. A divided tendril terminates each leaf. The racemes are long, and carry from six to ten flowers, and usually with a pair of flowers at the base. Each fully developed bloom measures about two inches across; the suborbicular standard as well as the petals are of a rich blood-red hue, but the keel—an inch or more long—is rose-coloured. It will be seen that both in the shape of the flowers and in the style of inflorescence Lathyrus splendens differs very largely from the garden varieties of sweet peas. Then also it is perennial, while the latter are annual, and this puts difficulties in the way of crossing the two. Unfortunately L. splendens has not as yet proved hardy at Kew, for though growing freely out of doors during summer, it does not survive our damp winter. In California the species flowers during the winter season, and at Kew it flowered in March, 1897; so that even if it eventually proved hardy, or half hardy here, the flowers would be injured and probably spoilt altogether if not protected. As a greenhouse, conservatory, or winter garden climber, Lathyrus splendens may, however, as it becomes more plentiful, be found serviceable. The flowers are remarkably brilliant and effective, more so than those of any other known species. We may add that seeds ripened on the Kew plant last year.

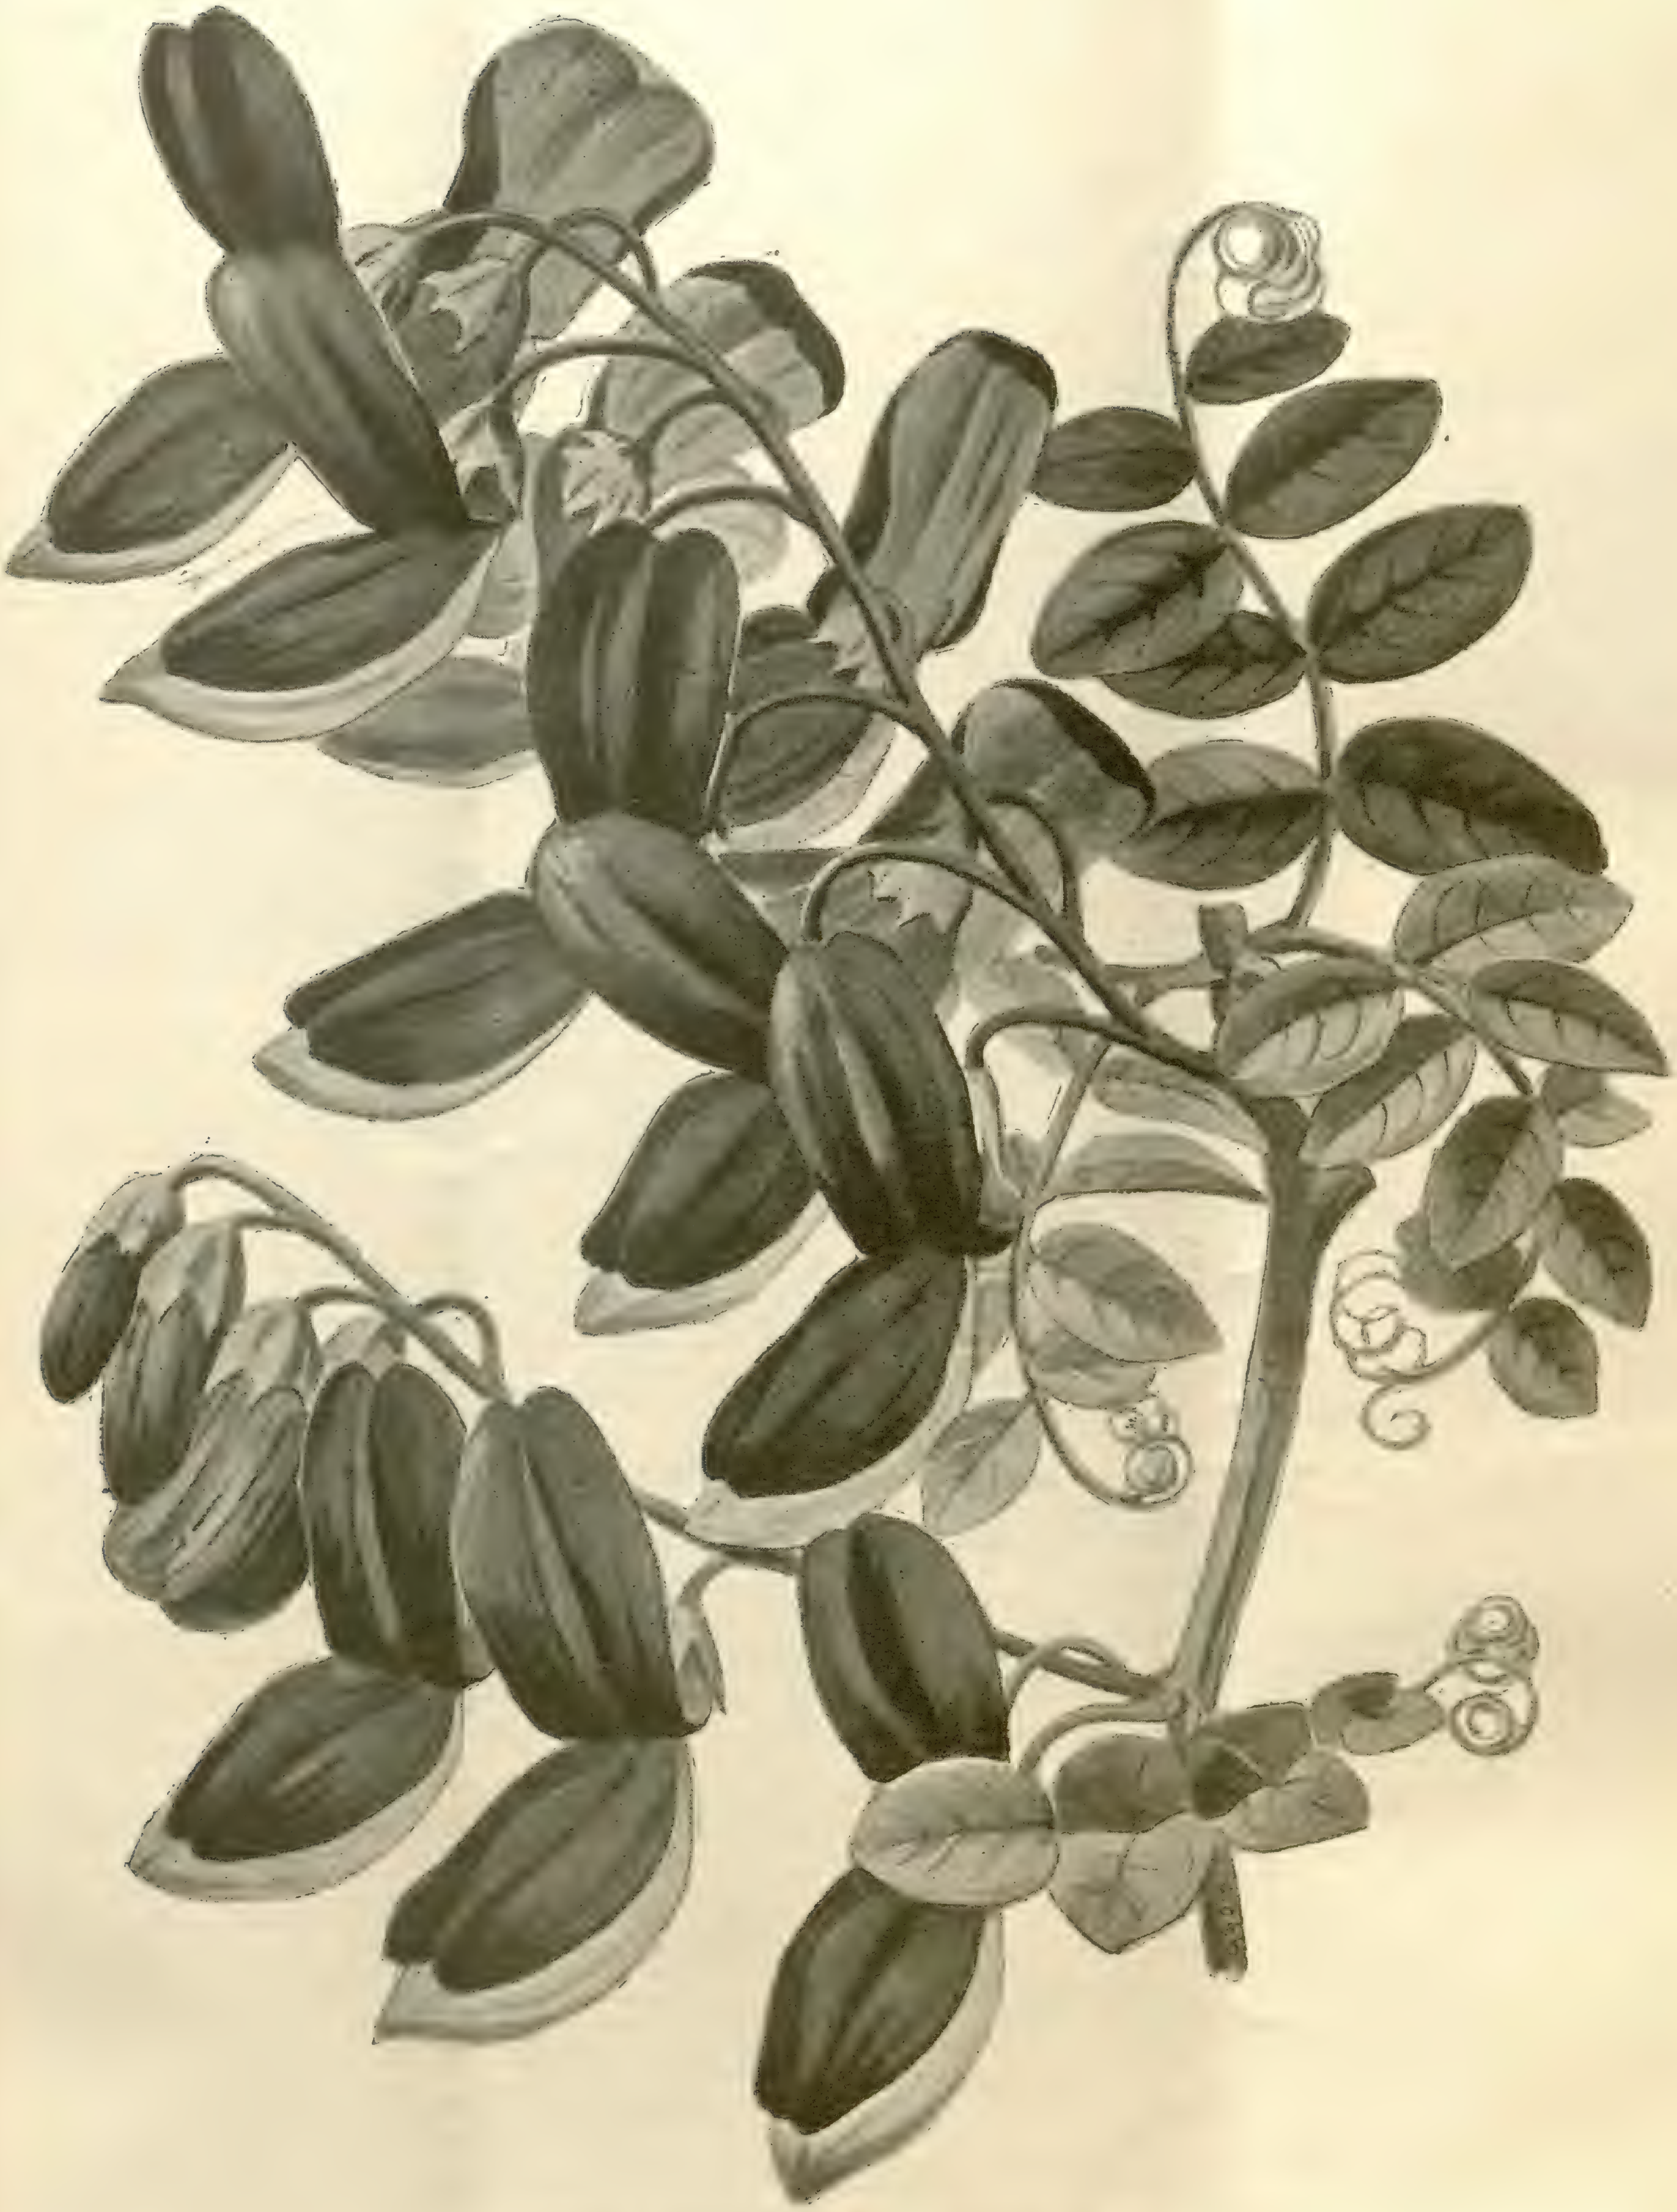
PRICES OF GRAPES.

THE following extract from a letter sent me by a Dorsetshire grower about the middle of January will, I am sure, be of interest to your readers. I have taken the liberty of adding a few comments:—

"Grapes have been very plentiful, but price I have thought very low. I planted one house of Gros Colmar alternately with Muscat of Alexandria and Canon Hall Muscat. The Muscats are not so strong as the others by a good deal, but the grapes set very fairly and were ready to cut first. The Canon Hall I was obliged to cut early because the berries burst; these sold at 1s. 9d. to 2s. 6d. per lb. Muscat of Alexandria came next—at the end of September, long before the Colmars under the same treatment were ready, so that for marketing I would not plant the same varieties together again. The Gros Colmars I was afraid were going to beat me at one time. Two vines, however, at the warmest end finished fruit finely, but altogether they cost me a lot for heat; the market price obtained was 1s. 3d. and 1s. 4d. per lb. Gros Maroc is easy to manage, and, with berries as black as one could wish them, sold at 1s. 6d. to 2s. per lb. Lady Downes made good vines, but it is not a good market variety, for though it finishes well the bunches and berries were small. They realise good prices, however, where flavour is of the most importance. We have a few pounds hanging yet (January 15). I had to syringe Gros Colmar in one house as it was over-cropped and had red spider badly, so that the grapes did not look very handsome, although they were very good to eat. I sold none of these at Christmas for less than 1s. 6d., while a few realised 1s. 9d. per lb. Black Alicante I like as it makes grand rods here from the top to the bottom of the house—sixteen to eighteen feet. These I cropped the full length, and the grapes finished well, sixteen to eighteen bunches to the rod; that is I fruited every other lateral. The berries were thinned severely, otherwise many of the bunches would have weighed two pounds. I have sold all my Alicantes at 1s. 9d to 2s. per lb."

With regard to this letter from a small grower I do not think the prices were low for the season of sale; on the contrary, I have no reason to think other growers have done better, and my experience is that at these prices grape-growing will pay alright. To realise over two shillings per pound grapes must be kept until the new year is fairly in, and then they must be good. The feeding of the Canon Hall Muscats was evidently too heavy just when the berries were colouring. The remarks anent Gros Maroc are of value as showing that the public will have a large-berried grape irrespective of a really first-rate flavour. Lady Downes is a fine, saleable market grape when it is well finished and kept; otherwise, what becomes of the tons grown over the Border? With regard to the Black Alicantes I suppose they did not swell at stoning time. This is very vexing, especially when thinned for keeping, and then not filling up. The weight was light, but probably the strong wood growth made the previous season was too great a tax. Better grapes will be had this season. The particulars with respect to Gros Colmar show that the grower was not well acquainted with them; they need much heat to finish well, especially if over-cropped, and our worst enemy—red spider—steps in. There is not the slightest doubt but that Gros Colmar requires its own special house and treatment to succeed. Except just in a very hot corner, for the sake of having late grapes, I never advise mixed planting. If growers realise an average of 1s. 6d. per pound for the last three months of the year they will not be doing badly.

Bottesford Vineries, Notts. STEPHEN CASTLE, F.R.H.S.



LATHYRUS SPLENDENS. (Flowers blood-red and rose.)

NOTES ON ORCHIDS.

CATTLEYA HARDYANA FANYAUIANA.

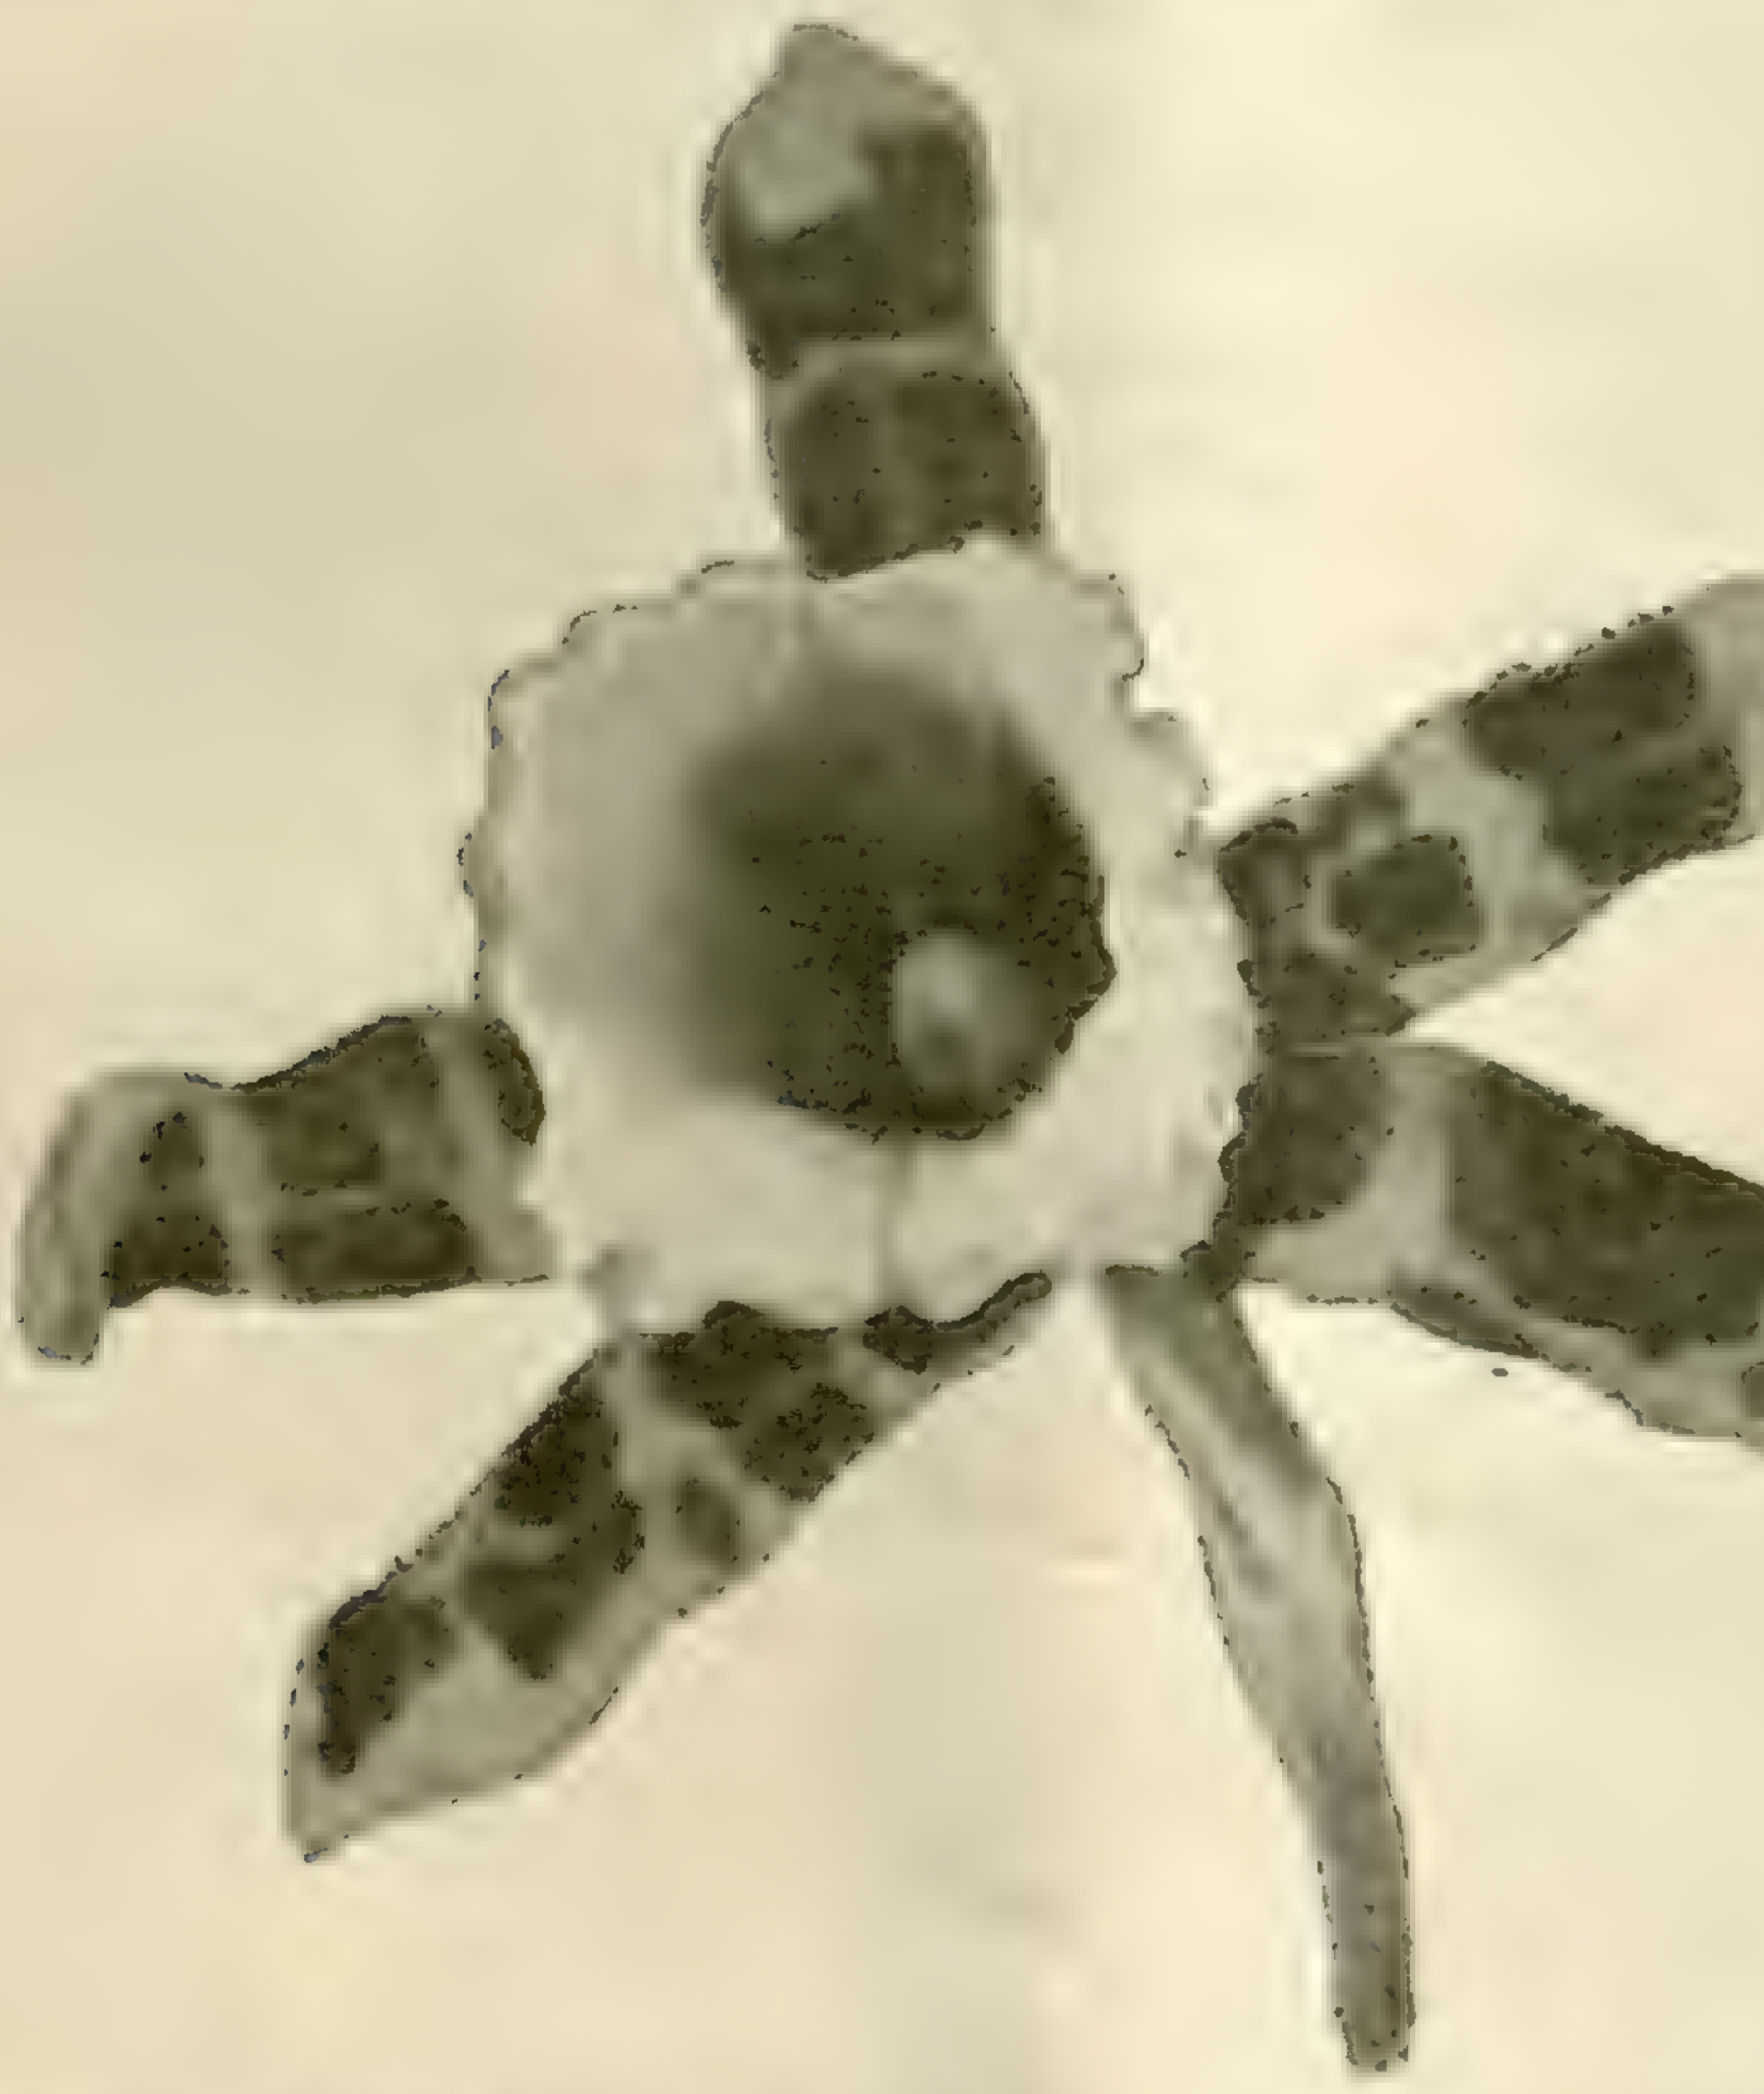
THIS is an extremely handsome form of the well-known natural hybrid; it first flowered with the Messrs. Linden, at Moortebeek. The broad and frilled petals are of bright rose colour, heavily vieded with reddish-rose; the petals are deep rose towards the margin, but paler along the centre. The lip is very fine, and has a rich red-purple apex and border; the side lobes are deep yellow, and the throat is purple veined with yellow, the latter colour radiating into the large frilled apex. This handsome orchid is dedicated to M. Oscar Fanyau, a French amateur orchidist. *Lindenia*, t. 593.

ODONTOGLOSSUM BICTONENSE.

This charming orchid is not met with in collections nearly so often as formerly, but it is, nevertheless, a fine plant when well grown, producing bold and erect spikes of pretty flowers. The latter have green sepals and petals elegantly marked with brown; the cordate lip is the chief attraction, it is large and of a clear and bright rosy lilac shade. We refer to this species now chiefly to draw attention to the coloured illustration of it and its white-lipped variety alba given in the current issue of the *Lindenia*, t. 594.

TRICHOPILIA BREVIS.

The genus trichopilia contains several species that are among the most interesting and handsome of orchids for basket cultivation. T. suavis and T. crispa are perhaps the best known and most generally cultivated, but those who admire these should not omit to include T. brevis in their collections. It is a most distinct species, having the broad campanulate base of the lip much shortened. The sepals and petals are greenish yellow, heavily blotched with deep chocolate. The large lip is pure white save for a light stain of pale yellow on the front lobe. The flowers are from three to four inches across, and most effective when several are produced together. T. brevis was introduced by Messrs. Linden and Co., Brussels, and first flowered with them in August, 1891. The Mexican house is a suitable structure in which to grow the species, and, as in the case of other members of the genus, it should be planted in a basket or pot, well drained, and raised so that there is little chance of the growths damping, and also so that the deflexed flower scapes may extend without hindrance. Not many orchids resent over-watering more than trichopilias. The present illustration represents a flower from a specimen exhibited by our able coadjutor, Mr. W. H. Young, orchid grower to Sir F. Wigan, Bart., Clare Lawn, East Sheen, at a recent R.H.S. meeting. An award of merit was granted.



TRICHOPILIA BREVIS. (Flowers greenish-yellow, chocolate and white.)

CYPRIPEDIUM INSIGNE JANUS.

The variations in the popular Cypripedium insigne seem to be endless and on one or more occasions we have objected to the excessive multiplication of varietal names that has taken place during the past few years. In the present instance, judging from an illustration in the *Lindenia* t. 595, there is little to complain of in this respect for the variety Janus is very distinct both in the heavy vein-like stripes of reddish brown along the greenish yellow sepals, and in the somewhat abnormal development of the ventral sepal. The latter is white with a wedge-shaped stain of greenish yellow extending from base to apex down the centre. The dorsal sepal has a pure white apex and border and a pale greenish-yellow base with brownish spots and dots. The lip is of the usual shade, with brown shading and shows up well against the ventral sepal.

CATASETUM SPLENDENS GRIGNANI.

A handsome orchid apparently intermediate between Catasetum Bungerothi and C. macrocarpum. It is a new variety that appeared last autumn in the establishment of Messrs. Linden and Co., Brussels. The tips of the creamy sepals are coloured reddish brown; the petals are broad, pale rose, spotted with red, and tipped with red Lip large and bold, white, with a fine deep orange centre: the bluntly spurred base of the lip is also tinged with orange on the outside. *Lindenia* t. 596.

LÆLIO-CATTLEYA RIDOLFIANA ARMAINVILLIERENSIS.

A handsome hybrid with large rosy flowers veined and stained with purple, and with a finely frilled and broad lip with a yellow throat and crimson purple radiating blotch on the purple ground. The original hybrid was raised in Italy between Cattleya Mossiæ and Lælia purpurata aurea. The present variety was raised by M. Jacob, the clever gardener to Baron Edmond de Rothschild, at Armainvilliers. It was obtained by crossing a very fine form of C. Mossiæ with L. purpurata, the latter being the seed parent.

BLACK CURRANT GALL MITE.

IN his annual report the zoologist of the Royal Agricultural Society states, and properly so, that the Black Currant Gall Mite (*Phytoptus ribis*) is undoubtedly at present the most serious pest which attacks black currant, and that many acres are annually rendered fruitless by its ravages, or robbed of a large proportion of their crop. The nature of the injury is almost too familiar to need description. The microscopic acarines infest the leaf buds, often causing them to become swoollen or gouty, through many of the mites may be present without causing much distortion. This pest seems to be very generally present, even in places where the infestation has not been severe enough to attract attention. For the purposes of experiment, black currant shoots entirely free from all suspicion of attack were required, and these were sought in gardens, both at Cambridge and at Southport, where no gall-mite infestation was suspected, but on every plant were to be found some of the characteristic galls. Much attention has been given to this pest during 1897, and though the results of the observations are largely negative, it is perhaps advisable to report them. Examination of infested buds at frequent intervals from January to November has invariably shown the presence of eggs and larvæ together with the mites. These were very numerous in the spring, and abundant for some time later; but in November they were few, though mites were still to be seen with unlaid eggs within them.

It seems likely that reproduction practically ceases during December—for one month out of twelve. If infested buds are simply cut open and shaken over a slide, some of the mites come out, but the eggs are mostly overlooked. The plan adopted was to slice the buds, cucumber fashion, and shake the sections up in a tube containing methylated spirits. The mites and their eggs were washed out, and formed a sediment at the bottom of the tube which could be examined under the microscope.

Many of the spring buds are so severely attacked that their growth is entirely arrested, while others, more slightly affected, succeed in putting forth their leaves. In both cases they are soon deserted by the mites, not one being visible where but a few days previously there were swarms. It seemed likely that, on the opening of slightly infested buds, numbers would be precipitated to the ground, perhaps to spread infestation by crawling up other stems. Experiments to ascertain this met with but little success. Dishes containing water were fixed beneath developing buds containing mites, and watched from day to day. A few mites were found in the water, but only a few. Eggs were not found, perhaps on account of their small size, for it is difficult to imagine how they could have done otherwise than fall.

Infested shoots, teeming with mites, were planted in flower-pots, the stems being passed through a sheet of black paper, upon which the mites could readily be observed. In the course of a few days mites in considerable numbers were certainly found on the paper, but they were all near the shoot, and did not seem to have fallen, but to have crawled down the stem, upon which others were found wandering. It is clear, then, that mites leave the buds as they begin to grow uninhabitable, and crawl elsewhere. This must happen extensively as the leaves are developing, and it is at that time, therefore, that spraying is likely to have the greatest effect. The statement of some entomologists, that the mites wander only in July, is therefore incorrect.

What becomes of the eggs I have failed to discover. The tremendous fertility of the mite is *à priori* evidence that a large portion of the brood is destroyed, and it is quite possible that, though I did not find them, multitudes of the eggs, turned out of their shelter, were blown away and failed to develop.

I was anxious to see if a healthy plant, placed in earth taken from beneath infested bushes, contracted the disease, but could not, at the time, find one completely free from infestation.

In conclusion, I have seen reason to doubt whether very severe pruning is altogether advisable as a means of combating this pest. The mites are certainly reduced in number, but so also are the available buds, and the enemy may survive in sufficient numbers to occupy all the buds available. It is probable that the old-fashioned and tedious plan of picking off the buds is the most effective. In November the plants are leafless, and the buds easily seen. It is not only the swollen buds which contain the mites, for many may be found in those which are apparently sound. In cases of severe attack I believe it would pay to send boys round in November to pick off into bags all the buds they find on the bushes.

Marguerite Carnations.—The varieties of this class of carnations are valuable for cutting, and may well be treated as annuals. If sown now good plants may be produced that will come into bloom after other established plants have done blooming in August. The seeds should be sown in small boxes or pans, filled with sandy loam and leaf soil, just covering the seeds, and stand afterwards on a mild hot bed until germination has taken place. As soon as the seedlings appear remove to cooler quarters and prick off into other boxes when large enough to handle. Plant outside in a prepared border eventually, and all the after culture required is a stirring of the surface soil occasionally and a removal of weeds. The flowers should be staked and tied as soon as necessary. If grown on in pots these Marguerite carnations are also very useful for autumn decoration. The pure white variety may now be obtained from seed sold in separate packets, and can be relied on to come fairly true. The white fringed blooms are very sweetly scented.—C. H.

Blue Chrysanthemums.—For the information of A. D. I may say that some years since I endeavoured by chemical application to change pink chrysanthemums into blue. In our soil, which is short of iron but contains abundance of lime, hydrangeas flower freely, but of the natural rosy pink hue. In pots, by the aid of sulphate of iron in the soil and frequent applications of alum water to the roots, I produced really blue heads of flower. I had several tints of blue, some exceedingly pale, really lavender, others deeper according to treatment. It is surprising what strong doses this plant will withstand of both iron and alum. So much so that some of the pots on the outside were covered with an exudence of the latter. As is well known, sulphate of iron is by far the best ingredient to apply to plants or trees for the restoration of lost chlorophyll or green colouring in the leaves. If, however, like some poisons, it is applied too freely it overreaches itself. The leaves on some plants we experimented with completely lost the whole of the green matter, and were quite of a bleached character. Regarding the changing of the colour of chrysanthemums by the same means I experimented with several varieties, commencing with Empress Eugenie, Hero of Stoke Newington, Alfred Salter, Beauty, Baron de Prailley, Comtesse de Beauregard, the Daimio, Bouquet Fait, and Hiver Flemie, but all to no purpose. Those who are conversant with all the varieties named will see that a variety of shades of pink were tested. In not one single instance did the plants yield to any variation of colour. After repeated experiments I came to the conclusion that blue chrysanthemums exist only in the imagination of enthusiastic artists.—E. MOLYNEUX, *Swanmore Park Gardens.*

Work for the Week.

WARM ORCHIDS.

In the early days of orchid cultivation, Cœlogyne cristata was much valued, and no doubt growers considered it a difficult plant to grow Experience has proved, however, that it is easily managed, and with the several improved varieties, we may now, by careful management, have a display from the cold month of December to the following June. At the present time scarcely any garden containing a greenhouse but has a few plants of this species. We do not prize it sufficiently, for it well deserves growing, and there is little to equal it in its season. The Chatsworth variety produces longer spikes and larger individual flowers than the type, although if grown in quite a cool house the blooms will not last so long as those of the species, owing to the labellum being of a more fleshy nature and sensitive to damp. The variety C. c. Lemoniana is the prettiest in the set. Then there is the Trentham variety, which, if retarded, will flower as late as June; we see them sometimes at our exhibitions. Then also we have the pure white form, which is one of the whitest of white orchid flowers. At the present time these must be watered sparingly, only sufficient to enable the bulbs to keep plump and support the flower-spikes. Remove plants in flower to the flowering house.

If any cattleyas have been imported attention must be given them in good time. Amateurs, as a rule, have an idea that plants must be potted in their rough and unsightly state just as they arrive. Such an idea should be abandoned. Cut up the specimens sufficiently to allow four or five bulbs to each lead, then give them a thorough washing with weak but warm soft-soapy water, cleaning the rhizomatous stems thoroughly in order to eradicate any insects or larvæ; examine each bulb carefully to see if there is any sign of cattleya fly, and if any be found cut the bulb clean away and burn it, as this is about the worst enemy cattleyas have. Next obtain crocks well washed in hot water, then prepare some good stout sticks long enough to reach from the bottom of the pot to the top of the longest bulb. Take a clean pot sufficiently large to allow each lead to come just inside the rim, the smaller the pot the better; place the ends of your sticks, say three or four, according to the size of pot required, in the pot, and place one large crock over the hole, and allow it to form a wedge for the sticks; half fill the pot with crocks, still using some as wedges, and make them so firm so that you can pick the whole affair up by one of the sticks; then take each piece of cattleya separately and tie firmly to the sticks, taking care to arrange each lead towards the edge of the pot and raised about an inch above the rim. After filling the pots to the top with smaller crocks give a good watering and place in a house where plenty of shade can be given, gradually bringing them to the light, and syringe overhead occasionally in order to plump up the bulbs. After-treatment will be given later.

The rebasketing of Lælia anceps, as before advised, may now be finished if flowering is over. Any cypripediums that have completed their flowering may be repotted, and large plants, where a stock is required, may be split up to the desired size. A good mixture for these is three parts of fibrous peat to one of good fibrous loam, with a little coarse silver sand, a little chopped sphagnum, a little charcoal, and a little old mortar, if at hand, all well mixed together. Attend well to the fumigating of all houses, give special attention to the ventilation, and keep temperatures as before advised.—T. Stafford, *Tyntesfield Gardens.*

CONSERVATORY AND GREENHOUSE.

The present is the best season of the year to attend to climbers and wall plants in the conservatory, as for the most part they will be in a dormant condition, and what pruning and cleaning is required can be done before new growth commences. Where properly cared for climbers in variety form a very pleasing feature in this structure; but it not unfrequently happens that for the want of a little timely thinning and regulating of the shoots, the growth becomes a crowded mass which obstructs light from the occupants below, encourages insect pests, and fail to meet the object they were intended for, viz., a graceful clothing of the rafters and roof supports. Cobæa scandens, both the green and variegated forms, is useful for large buildings, as it spreads rapidly; but care is necessary to regulate the shoots, or it is apt to become bare in places. Some of the more choice clematis are also useful for the same purpose, but the growths must be properly thinned out to allow of the flowers being seen to advantage. These quickly get into a tangled state, and where this was allowed to take place last season, pruning must be resorted to at once, or much damage will be done later when growth has commenced. Rather severe pruning of such things now may make the roof look bare for a few weeks, but it really becomes necessary at times to take such measures, not only for regulating future growths, but also for thoroughly cleansing them of mealy bug, which they are so subject to through the introduction of so many different plants into the house. After pruning out as much of the old wood as possible, syringe them thoroughly with water at not less than 80 degrees, and add a wine glass of petroleum to each gallon; opportunity being taken at the same time to scrub the roof down. This will give the plants a clean start again, and by a tie here and there and the removal of a few shoots where they are likely to become crowded, say once a month afterwards, they give a fine effect in the house. The rooting medium should also receive attention, taking out an inch or so of the surface soil and replacing it with good turfy loam, old mortar rubble, or charcoal. The latter is very necessary as it prevents the soil from becoming sour. For wall plants in the conservatory few things can equal and give a better display through most of the summer months than Bougainvillea glabra, especially when some of the longest branches can be trained to the rafters to allow the flowering shoots to depend in a natural way. The plants will have shed their foliage some time ago, and having been kept somewhat dry at the roots since, the needed rest has been afforded. All the thin wood should now be spurred back and sufficient leading shoots retained to cover the space allotted evenly. A good soaking of water will be necessary to thoroughly moisten the soil, and growth will commence at once.

Camellias, either growing in borders, tubs, or pots, will be all the better for careful pruning before they commence another season's growth. With some plants all that is necessary is to shorten a few of the shoots back somewhat to secure a well-balanced specimen. It is not necessary to loosen the surface soil if the plants are in a healthy condition, as this is not done without some injury to the numerous fibres. A sprinkling of fresh loam, with a few crushed bones added, after the border has been properly watered and beaten down firmly with the back of the spade, will encourage more surface roots as well as promote short-jointed growth, which is very desirable with these plants. Azaleas as they go out of bloom should be kept by themselves, where they can have proper treatment in the way of watering and syringing to encourage early growth. These, too, will be all the better for being slightly pruned into shape, as new shoots will form at once from the old wood, and more compact plants are obtained. It would be wise also to fumigate them once or twice, so as to kill any thrip that may be about them, and which quickly spreads and ruins the young tender foliage. These plants require a close warm house and plenty of syringing while they are making their growth. Such plants as Azalea mollis, and lilacs which have been forced, should also be cut back somewhat and encouraged to make new shoots in a warm pit, and afterwards gradually hardened before being put outside. Bulbs of different kinds will come on quite fast enough now in a close pit, and the less fire heat used the better, as the blooms will have more substance and last longer, especially in a cut condition. Roots of Solomon's seal if dug up now will provide very useful material both for decorating and for cutting, and by starting them now they will be ready by Easter without actual forcing. A good batch of spiræa, both S. astilboides and S. japonica, should also be started, as their white flowers are very acceptable at the season mentioned.—R. Parker, *Goodwood Gardens.*

THE FLOWER GARDEN.

With the exceedingly mild weather prevailing roses and other subjects are making an early start into growth. Nevertheless it will not be advisable to commence the pruning of either standard or dwarf roses for a few weeks, as the chances are that we may, as a set-off to the present mildness, have our winter in the spring months; and if roses are pruned thus early the lower buds start into growth, which, if pruning is deferred, remain dormant, and probably escape should severe weather occur later. It has been proved repeatedly that the little extra growth made and eventually pruned away has little, if any, injurious effect on the plant. Where growing against walls or fences roses and other climbers may be taken in hand now and receive the pruning and nailing necessary. With roses of strong growth as Rêve d'Or, Gloire de Dijon, Maréchal Niel, and others, the weak growths should be trimmed out, and the strong shoots nailed, or tied in, almost in their entirety, simply cutting away just the weak point of the shoot. It is surprising what a profusion of blossoms may be obtained from them when treated in this way, even of the first-mentioned variety which, when grown on the cut-back system, is a very indifferent bloomer. In the pruning of climbers generally note should be taken that the flowering wood is not removed, especially of clematis, as those of the Montana type flower from the ripened wood of the previous year's growth; the pruning of these should be deferred until flowering is over, when, if cut back without delay, flowering wood will be made for the next season. Somewhat similar treatment should be given to Jasminum nudiflorum and Chimonanthus fragrans that are now fully in bloom. Clematis of the Jackmanni type may be pruned hard back to a few eyes where employed for covering arches or for trailing over beds, and when so treated usually make strong growths as long as desired for this purpose, which flower freely.

Climbing plants in variety may still be planted, but unless plants can be turned out of pots this work should be finished at the earliest opportunity. For the south aspect the following are suitable: Ceanothus azureus and its varieties; Passiflora cœrulea and P. Constance Elliott; these should be given the warmest situation, and the ceanothus sheltered with a few branches or temporary covering in severe weather. Others are Bignonia grandiflora, the early-blooming Garrya elliptica, Choisya ternata, an evergreen plant of shrubby growth with sweetly-scented white flowers. The evergreen magnolias are suitable for planting against a high wall or building, being of strong growth, and if given a sheltered situation they are seldom injured by severe frosts in the southern counties. Their large sweetly-scented white flowers are much prized in late summer and autumn. The sweet Jasminum officinale and J. o. grandiflorum are also desirable subjects. In pruning these two should be cut within a couple of eyes of the old wood, the flowers being produced on the young growths. The later yellow-flowered J. revolutum, of stronger growth than the preceding, should be planted in a warm situation, and not be pruned too closely, and some of the strong young growths of the past season may be tied in to nearly their full length. For the rich coloration of autumn foliage Ampelopsis Veitchi and A. hederacea should be given a south or west aspect. Loniceras in variety, Escallonia macrantha, Forsythia suspensa and F. viridissima, Kerria japonica, and Wistaria sinensis are other desirable subjects. For covering a wall or fence with a north aspect Cratægus pyrancantha and C. Lelandi are excellent plants of free growth, and in this position both flower and set their berries in profusion, and the latter are effective through the dull winter months unless devoured by birds.

Where sub-tropical bedding is carried out some of the slower growing kinds used should be sown now. Canna seeds take some time to germinate, and before sowing they should be soaked for twenty-four hours in warm water. Grevillea robusta and eucalyptus seeds may now be sown, while ricinus and similar quick-growing subjects may wait a month yet, and then be quite large enough for bedding-out time. Stock roots of dahlias should be introduced to heat for the production of young growths for propagation. The latter should be taken off as soon as large enough to handle, and inserted in pots of sandy soil, and plunged in a moderate bottom heat.—C. Herrin, *Dropmore Gardens.*

HARDY FRUITS.

Old trees intended for grafting should now be headed down, as it is a good time to prepare for this work. Owing to the mild weather it will not be safe to leave scions for grafting any longer on the trees as the season is more forward than usual; the grafts taken should be a well-ripened shoot of moderate strength, and the name of each variety should be firmly attached to each bundle; these must be inserted half their length in a cool north border to retard growth, and should the soil be at all dry give moisture occasionally to prevent the bark shrivelling. It often happens that old fruit trees, indeed, younger ones also, in standard form are allowed to grow for years without pruning, with the result that fruits are small; now is a suitable time to thin out very thick growths and cross branches, but I am not advising wholesale mutilation, for this would make matters worse after the years of freedom; rather do a portion of the thinning yearly. In the case of plums much may be done to encourage fruiting by the removal of useless spray, encouraging fruit buds to form freely, and admit light and air. Newly-planted trees should be staked now the soil has settled, and I am greatly in favour of naming all fruits, as the labels from growers soon become unreadable or lost, causing much trouble later on. In all gardens correctly-named trees are interesting and educational. After a trial of many kinds of labels I find that metal ones with raised letters are very good; we use those made by the Stratford Label Company. For many years we used leaden strips with the letters punched in the lead, and these last well, but are not so neat as the others. For attaching labels to fruit trees it is best to use wire, as this is soft and pliable, but it is well to allow plenty of space; if copper wire is used place it so that it cannot impede growth. The labels in the case of wall trees may be nailed to the wall, and in the open may be placed on a small stake in front of the trees.

Apricots will soon be coming into flower, and if not yet nailed or pruned the work should be proceeded with. We find there is little to prune at this season, if the summer growth was regulated; but it may be necessary to reduce the spur growths, as these, if at all crowded, produce too many inferior fruits; those that are farthest from the wall should be removed first, as the apricot in its earlier stages needs protection. My remarks concerning the removal of spur growths are applicable to other fruits, notably apples, pears, and plums, as these often have far too many spur growths producing an abundance of small fruit which do not pay for storage. Apricots will now need protection, and if there is a good coping I am adverse to a thick covering of any kind, as such covering weakens the flowers. We rarely miss a crop with trees on a south-west wall, and, strange to relate, our best crop was after the coldest February and March I ever remember; but the trees were dry, and if the blossom is dry I do not think cold does so much injury as supposed. We usually protect with a double-inch mesh fish-net, and it is much better than a thicker cover, which excludes air. The growth of strawberries this year is earlier than usual, and any work in the quarters should now be attended to, and though I do not advise digging between the rows, it is necessary to fork up the surface to destroy weeds; it is a good plan with old beds to well mulch in the winter with decayed manure, and in February to cover the manure with soil, that is, lightly forking the surface and covering the manure. There is a great gain from winter dressings, as the new roots made early in the year are enabled to absorb the food given. I am not in favour of keeping old strawberries, believing the best results are secured from young plants; but all cannot follow this practice, so now is the time to give manure to enable plants to furnish heavy crops. Birds are this year a source of trouble with newly-pruned gooseberry and currant trees, and unless their depredations are prevented they will ruin the crop. Probably the best preventive is a strong dose of quassia with a liberal mixture of soot and fresh lime. This adheres to the trees, and will for a long time give the trees a rest, but it may be necessary to repeat the dose later, after rains or frost. I have seen black thread used with success in the case of a few trees. This, lightly entwined round the branches, will prevent their attacks; and, of course. netting over will be even superior to any other protection but it often happens one cannot spare the nets. All pruning and cleansing of fruit trees should be brought to a close as soon as possible, and wherever possible trees needing food may be given a mulch of decayed manure.—G. Wythes, *Syon Gardens*.

NEW BOOKS.

Lyonesse: A Handbook to the Isles of Scilly. By J. C. Tonkin and R. P. Row. Price 6d. (Beechings, Limited, 174, Strand, London.)—An admirable guide to the Scilly Isles, which, by reason of the enterprise of the inhabitants in developing their great natural advantages, have of late years acquired considerable importance. This handbook, although of a size that admits of its being carried without discomfort in the breast pocket, contains sufficient information on the natural features and historical aspects of the islands to enable the visitor to become well acquainted with their characteristics and the chief points in their history. It contains an excellent map and numerous illustrations. An introductory chapter is contributed by Sir Walter Besant, and in speaking of the charms of the islands he asks: "What time of year is best for visiting Scilly?" and in reply he says: "I have been there in spring and in autumn. I think that perhaps the early spring, when as yet there is no more than a thickening of the buds in the east and north of England, is the best time for a visit. For then the flower farms, though not at their best, can still show some of the flowers for which the islands are famous, and the air is softer than the cold winds of a London March, and it is fine enough and warm enough to spend the whole day long on the water cruising about in the roadstead or venturing outside to the west of Samson, Bryher, and Tresco. At this season, too, the walk round St. Mary's is stimulating and bracing; one can trudge along the highland ridge of St. Martin's in the cool wind, and across the downs of Tresco. One can point the prow outside to the shores of the uninhabited islets of Mincarlo and Minalto; to the rocks of the 'Western Isles'—Rosevear, Retarrier, Gorrigan—where the puffins collect on the rocks, and fly and swim, and dive, not yet gone off to their unknown summer homes; where the seals may be seen disporting in the waves; where the shags stand on wing, peak, and gable of the rocks. Nowhere around Great Britain is there such sailing among fairy islands of romance. At first the islands disappoint, the scenery is small, the roadstead is broad; no point is higher than one hundred and sixty feet; most of the cliffs and rocks are, indeed, very much less, but, day by day, as one is borne along from one islet to another, through narrow channels where the dark water races and roars, across broad stretches of ocean, along white sands, under black cliffs, with a breeze which never fails, over shallows of sapphire hue, the islands take such a hold of the imagination and the affections that they can never be forgotten or lost. Two things are necessary, that one should not come by one boat and go home by the next, but should make a stay long enough to know the place; and next, that the visitor must take the archipelago on its own merits, that is, he must not compare it for grandeur of scenery with one place, or for the luxuriance of vegetation with another. He must just walk about, sail about, look about, and be contented with what the islands have to offer." Sir Walter Besant further observes, "That if the softest, sweetest air in the world, air which takes from the Atlantic gales all their refinement and none of their blustering roughness, cannot please, what can? If lovely water, lovely rocks, lovely beaches of white sand strewn with purple shells, lovely gardens in which tree fern, bamboo, aloe, and prickly pear flourish as if the latitude were within Capricorn, with the mystery of cairns and prehistoric tombs, and the feeling, rather than the tradition, of ancient princes and royal burial grounds in Lyonesse; if these things, I say, cannot please thee, then, dear reader, come not to Scilly."

Modern Chrysanthemum Culture. By George Garner. Price 6d. (Blake and Mackenzie, Liverpool.)—A concisely written treatise on the cultivation of the chrysanthemum for exhibition and house decoration, containing much useful information.

Sweet Peas.—For the production of early blossoms a selection of varieties may be made and sown in pots for planting out; to make the most of small packets of new or choice varieties, sowing in pots is also to be recommended, as they can in this way be better protected from rats and mice than when sown direct in the open ground. Large sixty-sized pots should be used for this purpose, sowing six or eight seeds in each, standing them in a greenhouse temperature until the seedlings appear, and then transfer to a cold frame to harden off for a week or two, or until the ground is in a condition for planting them out. If space can be spared the kitchen garden is the place to grow sweet peas in specially for cutting purposes, and generally speaking the soil here is more liberally treated, and a succession of blossoms therefore the better ensured. The coloration of some of the newer varieties is very rich and effective. The following are all good: Blanche Burpee and Emily Henderson, two of the best whites; Mars and Meteor, crimson and crimson orange; Countess of Radnor, delicate mauve; Lady Penzance, bright rose; Princess Beatrice, pink; Countess of Powis, orange and purple; Monarch, crimson, wings blue; Lady Nina Balfour, delicate mauve: Captain of the Blues, purplish blue; and Coquette, deep primrose.—C. Herrin, *Dropmore Garden*.

WATERCRESS CULTURE FOR PROFIT.

In his exhaustive contribution to the current issue of the *Journal* of the Royal Agricultural Society on "The History and Cultivation of Watercress," Mr. Glenny gives the following particulars of the culture of the plant for market:—

Gravelly loam with a clay base is suggested as desirable, as it retains the water, makes a firm bottom, and furnishes nutriment for the plants. But, he points out, this will be of no avail without an ample supply of suitable water. The source of the water may arise in natural springs, clear, bright, and bubbling of its own accord out of the chalk, refreshing both to the eye and the palate, like crystal sparkling in the light; in some levels it may, of course, be needful to bore in order to obtain an adequate and efficient flow. The prosperity of the cress-bed depends mainly on the continuity, force, and regularity of the current. An abundant and perpetual stream is an absolute necessity, as the health of the plant depends on this condition. Without it the cress cannot be well nourished, the leaves will be stunted, and there will not be a bountiful growth throughout the season. The water affords protection from the heat of the summer and the cold of the winter, both of which extremes must be guarded against; the former burns the foliage and makes it sticky (hard); the latter freezes the stems and damages the crop irretrievably. A strong stream, maintaining a fair volume of water during heat and cold, is invaluable. The temperature of the water follows the temperature of the earth whence it originates, and should not fall below 51 degrees Fahrenheit. It does not answer to carry the cress-beds too far from the source, as the water naturally cools down as it travels away from the orifice. This factor limits the length of the cress-beds, for when the temperature of the air is lower than that of the water, the latter soon loses heat. Exposed to the cold atmosphere it falls below the required temperature, and the cress suffers in consequence. Were it not for this hindrance cress-beds would only be limited by the strength of the stream.

The depth of the beds must depend on the level of the spring; some are not above a foot deep, whilst others have been constructed at great expense, and are perhaps three or four feet below the level of the surrounding ground. There must needs be a slight inclination downwards from the spring, so that the water may flow gently through the cress. The fall of the bed should be extremely gradual, for if the declivity be sharp, the celerity of the current increases and washes away the soil, disturbing the plants. A gentle movement of the runlet from end to end of the cress-bed is what is required. The beds are made of no particular size, but mostly follow the configuration of the land; they may be six feet or thirty feet in breadth, but in the latter case longitudinal gangways will be required at suitable widths to carry off the crop when picked. These gangways are generally only banks of earth, but in some cases they are cemented on the surface, which makes the labour of gathering more easy in a rainy season.

Little bridges of rude planks are constructed across the beds, whilst dams are erected in suitable places to hold back the water at ordinary times, and to give opportunity to flatten down and submerge the plants in severe weather. Different practice prevails in this respect, as the severity of the cold is most felt in exposed situations. In certain months of the year, when the demand for cress is slack, the beds are cleaned out, and brook water may be utilised for irrigation, but facilities must be at hand to divert all subsidiary supplies at the approach of cold weather. Careful precautions should also be taken to keep out storm-water, and special channels must be provided where cress-beds from their level and situation are liable to flood. It may be advisable to construct a tunnel or culvert of a considerable length when there is backwater that may inundate the cress-bed. The best authorities recommend the annual cleansing and replanting of beds. This operation, which involves considerable expense, should be executed during the slack months of August and September.

The tops of the cress are first gathered and stowed away in a convenient place, sheltered from the sun and wind, until required for replanting. The dykes are then thoroughly bottomed out and the muddy soil removed, with all the old roots, weeds, and living creatures it contains. This process is followed by a careful levelling of the bottom, and a stream is allowed to flow for a sufficient time to thoroughly scour out all impurities. Everything is now ready for replanting, which is carried out in the following manner. The cut cress is carefully laid down in rows or spread broadcast on the ground, being sometimes secured by large stones where it is in danger of being shifted from its position. It is advisable to turn on the water sparingly in the first instance, for fear the plants should be disturbed; but in the course of four or five days the young rootlets will begin to strike and to take hold of the ground.

All this work needs skilled labourers who have had experience in the business, and they must be specially equipped for their task. The most important part of their outfit is the boots, which are provided by the employer at a cost of from 44s. to 60s. per pair, and are similar to those used for marsh-work. In addition to the expense of cleansing, the laying down a cress-bed would cost 6s. or 8s. per perch, if the plants were purchased. In order to procure fresh shoots for this autumn plantation, it is an approved plan to lay down some beds in March, and set them apart for this purpose. The clean plants from these rearing beds will be vigorous and free from weeds and other impurities. Small brooks and ditches inconveniently situated for market-work are utilised for the purpose of obtaining fresh plants.

Readers will naturally ask what it would cost to construct a cress-bed. We have already seen that the purchase of plants is a large item. The preparation of the ground is a more serious matter still. Much depends on the situation of the land, the irregularities of the surface to be overcome, and the level of the field or meadow in relation to the springs which it is desired to utilise. If the task is merely to shape out, to straighten, to take off the angles, and level the bottom of a ditch, so that the stream may have a gentle, steady swing, then 4s. or 5s. a perch might suffice.

The formation of large cress-beds to any extent is a heavier undertaking. There is the excavation of and the moving away of the surplus earth, making a true and correct incline to regulate automatically the flow of the stream, and this may soon involve considerable expense. I was shown a cress-bed of extensive proportions, constructed in 1887. and named the Jubilee bed, which cost as much or more than the value of the freehold. This illustration did not convey precise information, but gave a conception of a big outlay. The cress-bed was in some parts four feet below the level of the surrounding garden, and was rather an exceptional example.

To take a medium figure, perhaps it would cost £90 to £100 per acre in the formation of the beds, and with the plants at £1 per cwt., or £20 per ton, of which nearly two tons would be required to thoroughly plant an acre, the further cost would be £40. Thus £130 or £140 would be the rough estimate arrived at. The best pulled plants, if purchased, are difficult to acquire, though not costing so much when supplied on the farm. When the work is done by the occupier himself these alterations are carried through in an economical way, and for much less cost than any contractor would attempt them. Yet, after due consideration, I feel that, without a thorough knowledge of the surroundings of each case, such estimates must be rather conjectural and hypothetical.

The judicious marketing of the cress is an important problem, and needs much attention and forethought. London claims the first consideration, as the largest consumer, but the big towns in the provinces must be remembered. The probable demand must be gauged as far as possible, or the markets would certainly be glutted. The gathering and packing of the crop are mainly done by men, whilst women take a part in tying up the bunches. In cutting the cress, the men in big boots wade through the beds, having long boards to stand on when the depth of the water is abnormal or the bottom of the bed is treacherous. The use of boards has also the advantage of pressing the roots of the plants into the soil, and flattening down the stems and foliage under the water. Careful workmen are most particular in selecting the forward stems, which should be gathered singly, or, at most, two or three sprigs at a time; the more cautiously this is done, the sooner the bed is ready to be culled again. The picked cress should be carried in baskets or half-load baskets to the shed, where it is washed free from duck-weed or any trivial impurity. Women take up this department, and tie the cress up in small bunches at about ¼d. per dozen, and skilled hands often earn 2s. 6d. per day. Raffia, the epidermis of the leaves of Raphia Ruffia, which reaches us from Madagascar, via Mauritius, and also of Raphia tædigera, which comes from Brazil, is now largely imported for tying purposes. The cost of the raffia ranges from £40 to £50 per ton. The cress, after tying, has to be packed in baskets called flats, which contain about eighteen dozen bunches. The weight of a flat varies according to the size of the bunches, which again depends on the season; some growers make them up about half a hundredweight in the flat, but there is no uniform weight for all districts.

ANSWERS TO CORRESPONDENTS

The Wettest Village in England.—S. C., Sefton: We believe that the questionable honour of being the wettest village in England belongs to Seathwaite, at the head of Borrowdale, in Cumberland, Writing from memory, we believe that the rainfall there comes nearly up to one hundred and fifty inches in some years.

Caustic Soda and Potash.—L. T., Cookham: It is too late to dress the fruit trees with the mixture except on the trunk and bases of the stout branches, as the buds are now too prominent. Unless put on carefully the mixture would injure the grass below, though it is not likely to actually kill it unless large quantities of the solution are used.

Zonal Pelargoniums.—F. B., South Croydon: You should be able to grow zonal pelargoniums to flower in the autumn and winter in the structure you refer to provided you have pits or frames for their cultivation during summer and early autumn. If fogs are very heavy during the winter in the locality in which you reside it will be almost useless to grow these plants for winter flowering, as the results will in a large measure be spoiled.

Chrysanthemums.—A. B., Ashford: Not many really first-rate chrysanthemums are included in the list you send, but you might very well try the following: Mrs. John Shrimpton, Mrs. Briscoe-Ironside, Baron A. de Rothschild, Mons. G. Biron, Arona, Olive Oclee, and Hairy Wonder. These are the best of the set, and should only be included after you have made sure of the leading exhibition varieties, and the best of the new ones described in our columns during the past season.

Tobacco Water.—W. H., Leeds: There are several ways of making tobacco water for killing aphides and other plant pests. As tobacco and tobacco paper differ in strength it is always best to try the mixture with some moderately tender plant of little consequence unless the quality of the tobacco is known. If this be not done there may be a loss of valuable plants. A good mixture is made by steeping four ounces of coarse tobacco in a gallon of soft water for several days, stirring it occasionally; then strain the liquor and add to it half a gallon of hot water in which two or three ounces of soft soap has been dissolved. This is a good mixture for dipping.

Ardisia mamillata.—C. P. C., Wexford: This ardisia is a Chinese plant, and one that on the whole requires warmer treatment than A. crenulata needs. It is dwarf and has very distinct foliage which attracts as much attention as do the berries. The latter are freely produced but do not show themselves to the same advantage as in the case of the better known Mexican A. crenulata. A. mamillata is easily grown in a stove, but should be kept near the glass in its earlier stages. The genus ardisia is by no means so small as you suppose. There are a considerable number of species natives of China, Japan, Guiana, the Canaries, several parts of India, Costa Rica, Antilles, Sumatra, &c.

Names of Plants.—H. F. C., St. Albans: 1, Daphne Mezereum; 2, Hamamelis virginica; 3, Lonicera Standishi.

R. H., Croydon: 1, Primula floribunda; 2, P. obconica.

E. H. R., Reading: 1, Adiantum concinnum latum; 2, A. cuneatum Le Grandi; 3, Pellea cordata; 4, Davallia pentaphylla; 5, D. pallida, known in gardens as D. Mooreana.

T. Y., Scarborough: 1, Saxifraga sarmentosa; 2, Cyperus alternifolius.

R. C., Truro: Polygala Dalmaisiana is the current garden name of the specimen sent, but if you wish to be up-to-date you should label it Polygala myrtifolia grandiflora.

Communications Received.—R. H.—E. N. R.—H. F. C.—T. Y.—R. C.—W. H.—A. I. F.—C. P. C.—C. B.—A. B.—S. C.—W. W.—W. H. L.—C. S.—"Lux"—J. C. T.—H. C. P.—J. L.—A. J.—W. W.—I. B.—L. T.—M. H. W.—T. W. T.

STARTLING NEWS is daily coming to hand of sad accidents, murders, and minor criminal offences, but it is astonishing that thousands of people die in our midst every week, and no notice is taken of the fact. Yet such a terrible calamity could be prevented if more frequent attention was paid to the laws of health. If people would only deal seriously with slight ailments they would not develop into fatal diseases. There are thousands of persons killed yearly simply through neglect. Holloway's Pills and Ointment can prevent as well as cure disease, and if they were used according to directions, there would soon be a decrease in the death-rate. They can be obtained from all chemists and medicine vendors.—[ADVT.]

ROYAL HORTICULTURAL SOCIETY, FEB. 8.

THE fine display that met the gaze of the numerous visitors to the Drill Hall on the above date must have been most welcome. The last few days had been very cold, but here were spring flowers in all their beauty; roses, too, reminded us of coming summer, orchids of varied hues delighted the senses of sight and smell, while fruits made many long to exercise their sense of taste. It was a first-rate display throughout, and also a large one. Novelties were not over plentiful, but not many of these successfully passed the examination of the committees.

FLORAL COMMITTEE.

The bulk of the work devolved upon his committee, as there was a considerable number of exhibits brought forward, though none save Anthurium Dr. Laurence merited a certificate Primulas, ferns, early spring flowers, camellias, and euonymuses were the leading features.

A charming exhibit was the large group of freesias that came from Mr. Mowbray, gardener to Major the Hon. H. C. Legge, Slough; the specimens were beautifully flowered, and the fragrant blooms were of the purest whiteness. Mr. George Mount, Canterbury, staged two dozen particularly handsome and fragrant flowers of Catherine Mermet rose; for the season these blooms were remarkably large and substantial. Messrs. R. and G. Cuthbert, Southgate, had an attractive display of bulbous plants; the straw-coloured Roman hyacinths showed up well amid a collection of crocuses in all shades of blue, purple, cream, and white, but no yellow ones; Scilla siberica and its white variety were freely flowered. A handsome bank of primulas came from Messrs. J. Veitch and Sons, Chelsea; these were all finely developed specimens, and the varieties were very distinct; Chelsea Rose, Fringed Red, Veitch's Salmon, Gigantic Rose, and Chelsea Crimson all attracted attention by reason of the size of the flowers and trusses and the beauty of the colouring; the Star primula, and numerous double forms, including the handsome and rich Double Crimson and Double Salmon, were staged amid other varieties; baskets of blue primroses flanked the other primulas. Mr. J. Russell, Richmond, sent large baskets of the beautiful and early flowering mezereons, staging Daphne Mezereum flore-alba, and D. M. atro-rubra, the latter very fine indeed.

If anything could induce horticulturists to again take up the culture of camellias on a large scale it should be the grand exhibits that Messrs. W. Paul and Son, Waltham Cross, frequently stage at the Drill Hall early in the year. On this occasion, the clean handsome foliage on the shapely specimens, and the fine bold flowers in all shades of red and rose and white could not fail to draw attention. It is needless to particularise the varieties, but perhaps Marchioness of Exeter was as attractive as any. Mr. John Russell, Richmond Nurseries, Richmond, put up a splendid lot of euonymuses, a class of plants that needs bringing more before the public; there were numbers of neat examples of E. microphyllus, E. radicans Silver Gem, E. latifolius albo-marginatus,and standards of E. japonicus ovata-aurea, and E. j. ovata-alba; the bright shining foliage and clear colours were most attractive. Messrs. J. Peed and Sons, Norwood, put up a collection of forced plants, staging lily of the valley, lilacs, genistas, daffodils, &c., with cyclamens, begonias, Saintpaulia ionantha, and a few cypripediums and cinerarias.

Messrs. J. Hill and Son, Lower Edmonton, made up a pretty and interesting exhibit of ferns, showing large specimens of Davallia hirta cristata, Asplenium Nidus-avis, Adiantum Farleyense, Nephrolepis davallioides furcans, Davallia Tyermanni, &c.; in front of these were staged baskets of smaller plants of such interesting subjects as Pteris longifolia Mariesi, Gymnogramma peruviana argyrophylla, Adiantum rhodophyllum, A. concinnum, Cheilanthes elegans and C. hirta Ellisiana, Pteris serulata gracile, &c.; Lygodium scandens was not the least interesting plant in this group of ferns. An extensive exhibit of primulas from Messrs. H. Cannell and Sons, Swanley, attracted a deal of attention and was greatly admired. The Star primula occupied a prominent position, as did Lady Whitehead, a new cross from it. All the plants were splendidly flowered, and the several trusses made up fine pyramids of bloom; Lady Marsham, white; Mrs. R. Cannell, white and orange; Swanley Giant, deep purplish red; Cannell's Pink, and Cannell's Red, and Victory, a fine purple, were among the best.

Some glorious branches of Bougainvillea spectabilis shown by Mr. W. B. Camm, gardener to the Duchess of Cleveland, Battle Abbey, were admired as much as anything in the show, the flowers being crowded on the growth, and of the richest colour; Bignonia venusta, from the same source, was also finely represented. Two baskets of flowering sprays of Amygdalus Davidiana alba came from Messrs. J. Veitch and Sons, Chelsea. Spring flowers from Mr. T. S. Ware, Tottenham, were greatly appreciated; daffodils in pots, especially Henry Irving and Golden Spur, were very fine; irises were represented by I. reticulata in pots and pans, I. stylosa, and I. histriodes; crocuses, scillas, hellebores, saxifragas, Primula denticulata, a tiny plant of Adonis amurensis, Leucojum carpaticum, Anemone pulsatilla, and some blue primroses combined to make up a beautiful and very interesting collection. Messrs. Paul and Son, Cheshunt, sent branches of Alnus glutinosa aurea, bearing an abundance of male catkins, Helleborus colchicus in variety, H. orientalis, H. lutescens, Cyclamen coum, Pulmonaria azurea, and Saxifraga lutea purpurea, were all well represented; the hellebores were specially attractive. A big bunch of anthurium spathes, the variety, Dr. Lawrence, with spathes seven inches by eight inches and of a salmon-pink shade; the tip of the spadix yellow; leaves very large, was shown by Mr. Bain, gardener to Sir Trevor Lawrence, Bart.

Messrs. R. Veitch and Sons, Exeter, sent two flowers of Magnolia Campbelli that opened in the open air at Exeter. Messrs. R. Wallace and Co., Colchester, sent some pots of Iris reticulata, I. r. Krelagi, I. histroides, and the charming I. histrio. A very fine soft scarlet single pelargonium was submitted by Mr. R. Parker, Goodwood Gardens, Chichester, but failed to gain an award though both pips and trusses were large and shapely. Crinum zemensis with two spikes of white flowers came from the Rev. W. Shirley, Fareham.

ORCHID COMMITTEE.

Dendrobiums and cypripediums formed the bulk of the orchid display on this occasion. Both trade growers and amateurs were fairly well represented for thus early in the season.

From Messrs. J. Veitch and Sons, Chelsea, came a pretty group of orchids, dendrobiums making up the bulk of the exhibits; D. Cordelia flavescens, D. euosmum, D. Endocharis, D. Schneiderianum, D. Domini, D. aureum, and D. crassinode, made a charming display, and among them also contributed a delightful fragrance; cypripediums well shown were C. Godseffianum, C. Adrastus—the fine hybrid between C. Leeanum and C. villosum Boxalli—C. Creon, and C. Lathamianum, the latter carrying ten very fine flowers. Epidendrum O'Brienianum, Cirrhopetalum picturatum, and Platyclinis glumacea valida, were other interesting orchids shown by the Chelsea firm. Messrs. H. Low and Co.'s contribution included several good forms of Odontoglossum crispum, Laelia cinnabarina, L. anceps alba, Cypripedium Preweti, a new hybrid having C. villosum as one parent; Cattleya Trianæ plumosa, a very pretty form with rich, violet purple tips to the petals; Dendrobium nobile Ballianum, a white variety;

D. Luno, and D. Venus, were staged amid various odontoglots, dendrobes, platyclinis, and cypripediums, &c. Cœlogyne cristata in variety, made a good show in a group staged by Messrs. B. S. Williams and Co., Upper Holloway; the curious Cypripedium Carnosianum, C. Ashburtonianum superbum, C. Pitcherianum, Williams' variety, C. euryandrum, and C. Sallieri, and a deeply-coloured form of C. Spicerianum, were especially noticeable; Sophronitis grandiflora was very attractive in this exhibit. Mr. Miller, gardener to Lord Foley, Esher, staged a group of the typical Cypripedium insigne; a freely-flowered lot of plants.

Lælia anceps Waddoniensis was shown by Mr. Harris, gardener to Philip Crowley, Esq., Waddon House, Croydon; this is a very handsome white sepalled and petalled variety, with golden crest and pale veins in the throat. Mr. W. Murray, gardener to Norman Cookson, Esq., Wylam-on-Tyne, sent a few of his wire orchid stands, showing the manner in which they are used. Mr. Rolfe, gardener to P. B. Tubbs, Esq., sent a fine Cattleya Trianæ, with a wonderfully fine lip. Odontoglossum Rossi rubescens Rosefield var. is a beautiful odontoglot, with handsome deep chocolate markings on the rosy segments; this came from De Barri Crawshay, Esq. Messrs. J. Veitch and Sons showed Lælio-cattleya Myra, a fine golden form obtained by crossing L. flava and C. Trianæ; Calanthe Ariadne, Cypripedium Enid (C. bellatulum crossed C. Spicerianum) and C. Lathamianum superbum, a magnificent orchid. Mr. Empson, gardener to Mrs. Wingfield, Ampthill, sent a very good form of Dendrobium nobile. Mr. Norman Cookson showed a new calanthe, a gloriously rich red form, with crimson shading; Mr. Cookson also submitted Cypripedium Ceris, C. Sandero-superbiens, Lælio-cattleya Doris, and spikes of Cypripedium Morganiæ and C. Youngianum superbum, both carrying very fine flowers. Messrs. Sander and Co., St. Albans, sent Lycaste Skinneri alba, an ever welcome orchid; Cattleya Triana, with violet purple apices to the petals; Oncidium splendidum and Calanthe rubens alba, a pretty small-flowered form, but with long and freely flowered spikes. Mr. Chard, of Clapham Common, sent a richly coloured form of Cypripedium Chapmanni, and Mr. T. Patterson, gardener to S. G. Lutwyche, Esq., Eden Park, Beckenham, showed a bold form of Cypripedium villosum. Mr. Stevens, gardener to W. Thomson, Esq., Walton Grange, Stone, Staffs, sent a pair of handsome odontoglossums—O. excellens spectabile, with yellow flowers spotted with chocolate-red, and O. hystrix grandis, a superb form with fringed segments.

Mr. W. H. White, orchid grower to Sir Trevor Lawrence, Bart., staged some very interesting orchids, and good specimens in every case of Odontoglossum crispum, O. Andersonianum, a grand variety, and with splendid branched spikes; Cattleya Percivaliana, a lovely form; Dendrobium nobile Burford var., D. chrysodiscum Hebe, D. endocharis; D. Juno, D. Burfordiensis; Brasso-cattleya Lindleyana, Angræcum pertusum, a quaint orchid, with stiff spikes of small white flowers; this specimen has been at Burford Lodge since 1878. Masdevallia polysticta purpurea, Angræcum eburneum, and Sophronitis grandiflora also graced the collection. Mr. W. H. Young, orchid grower to Sir F. Wigan, Bart., East Sheen, showed Lælia pumila præstans, and the curious brown-spotted Odontoglossum Schillerianum.

FRUIT COMMITTEE.

A small number of exhibits of fruit and vegetables were forthcoming on this occasion.

Apples in fine condition came from Mr. George Mount, Canterbury; these were splendidly kept examples of Cox's Orange Pippin, King of the Pippins, Court Pendu Plat, Bess Pool, Bismarck, Mère de Ménage, Gloria Mundi, Wellington, Lord Derby, and Northern Greening; these and Blenheim Orange were all firm and of fine colour and quality. Mr. Miller, gardener to Lord Foley, Ruxley Lodge, Esher, sent two boxes of good mushrooms grown outside under straw; Mr. Miller also sent a few dishes of late apples and pears. Mr. J. Clarke, gardener to S. Keene, Esq., Barnes, gained a cultural commendation for a basket of very good mushrooms. Mr. Thomas, Royal Gardens, Windsor, gained an A.M. for his cucumber, named Every Day, a cross between Rochford's Market and Dickson's All the Year Round. Messrs. Sutton and Sons staged two baskets of fine firm heads of their Superb Early White broccoli, a famous winter variety; they also showed a basket of Bountiful peas, grown without heat under glass from seed sown October, 1897.

For the Veitch flavour prizes, Mr. Divers, Belvoir Castle Gardens, was first for apples, with Cox's Orange Pippin; Mr. Woodward, second, with Calville Blanche. For pears these gentlemen reversed positions, Mr. Woodward, Barham Court Gardens, Sevenoaks, winning with Passe Crassane; and Mr. Divers coming second with Olivier des Serres.

MEDALS AWARDED.

On this occasion, a sub committee, consisting of three members of each of the three committees, were deputed to make awards to the groups. Their finding was as follows:—Silver-gilt Flora medal to Messrs. W. Paul and Son, Waltham Cross; silver-gilt Banksian medal to Mr. J. Hill, Lower Edmonton; ditto to Mr. W. H. White, orchid grower to Sir Trevor Lawrence, Bart.; silver Flora medals to Messrs. J. Veitch and Sons, Chelsea, and Messrs. Cannell and Sons, Swanley; silver Banksian medals to Mr. Mowbray, gardener to Major the Hon. F. C. Legge, and Mr. G. Mount, Canterbury; Bronze Banksian medals to Messrs. J. Peed and Sons, Norwood; Mr. Miller, gardener to Lord Foley, Esher; and to Messrs. Hugh Low and Co., Clapton.

ANNUAL MEETING.

The annual general meeting of the society was held, as usual, in the Lindley Library. The President—Sir Trevor Lawrence, Bart.—occupied the chair, and was supported by the Council. There was a very large attendance. The usual formalities having been disposed of, Messrs. Harry Turner and George Bunyard were appointed scrutineers of the ballot. A vote of thanks to the retiring councillors was proposed by Mr. H. J. Pearson, Beeston, and seconded by Mr. George Gordon, each speaker referring to the able services rendered by Mr. James Douglas for so many years past.

Sir Trevor Lawrence then moved the adoption of the report—already published in our columns—and passed in review its salient features. The great success of the Drill Hall, Temple, and Crystal Palace shows, and the large increase in the number of Fellows during the past year were matters dealt with at length. Sir Trevor remarked that he hoped some day the society would be able to settle the question of a Home for Horticulture; they had a nice surplus, and if only the members would subscribe two guineas per year instead of one, he thought it would not be many years before their treasurer would tell them they might have a hall such as they all desired. Referring to Chiswick, he eulogised the services of Mr. S. T. Wright, the superintendent, and stated that during the present year the Council hoped to have all glass structures there put into proper repair. A gathering of the committees would again take place at the Chiswick Gardens this year. He considered no society gave its members such a good guinea's worth as did the R.H.S., the *Journal* was worth the money, and in its production they were greatly indebted to their secretary, the Rev. W. Wilks. In addition to this there was free admission to the shows and to Chiswick, and the Fellows could now have the services of Dr. Voelcker, the celebrated chemist, at half the usual charges. Sir Trevor stated that the catalogue of the Lindley Library would soon be completed. In conclusion, he tendered the thanks of the Council to those who had provided scholarships, to Messrs. Grahame and Sherwood for special prizes, and to the lecturers of the past season.

Mr. A. Dean complained of the action of the Council in interfering with the privileges of the members of the several committees. On that day there had been several members selected from each body to form a composite committee for making awards to the groups at the Drill Hall. He considered each committee should perform its own work, as it was better qualified to do that than to interfere in the work of the others. He thought there would be no objection were the Council to express a wish that each committee should depute a sub-committee of its own members to adjudicate upon groups of produce coming under its cognizance, so as to expedite the work. It was evident from the tone of the meeting that Mr. Dean's remarks were opportune. Sir Trevor Lawrence said that the matter was coming before the Council, and he had already seen it necessary to suggest that each committee select its own sub-committee to examine the groups. Mr. Richard Dean said that the Floral Committee deeply felt the action of the Council in this matter, for that body had invariably done what the president had now suggested as advisable whenever there was a large amount of work to be done. Dr. J. Ince alluded to the report as a most favourable one, and eulogised the work done by the secretary. He considered that as a society they did not get a profitable return from the Chiswick Gardens either in income or educational results. He thought the medals had been too freely awarded at the Drill Hall meetings; but the meeting objecting to this, Dr. Ince proceeded to say of course it was but right that those who helped to produce the displays should have some recognition. Dr. Masters seconded the adoption of the report, and said that he still held to a formerly-expressed opinion that Chiswick did not yield such valuable results as it should in respect to horticultural education and advancement. He thought that Dr. Voelcker's services would prove of great value. The report was then adopted.

The scrutineers then handed in their report, which showed that Sir Frederick Wigan, Bart., Mr. J. Gurney Fowler, and Mr. James Hudson had been elected to fill the vacancies arising in the Council by the retirement of Messrs. N. C. Cookson, J. Douglas, and T. Gabriel. The official business having concluded, Mr. B. G. Berry, Boughton, Fareham, brought forward the question of the Black Currant Mite, which, he said, was crippling the small-fruit industry of Kent, and if not speedily checked would result in the growers having to entirely give up the cultivation of black currants. He thought the combined wisdom of the Scientific Committee might with advantage be brought to bear upon this subject. Sir Trevor stated that the question would be brought before the committee, and asked Mr. Berry to remain and give evidence. A vote of thanks to the President for presiding, proposed by Dr. Ince and seconded by Mr. G. Wythes, concluded the proceedings.

ENGAGEMENTS FOR THE ENSUING WEEK.

AUCTIONS.

TUESDAY, WEDNESDAY, THURSDAY, AND FRIDAY, FEBRUARY 15, 16, 17, AND 18.—Lilies, Azaleas, Orchids, Roses, Plants, Shrubs, &c., at Protheroe and Morris's Room.

MONDAY, FEBRUARY 14.—Border Plants, Shrubs, Roses, Fruit Trees, &c., at J. C. Stevens's Rooms.

WEDNESDAY, FEBRUARY 16.—Great Rose Sale, also Plants, Fruit Trees, Shrubs, &c., at J. C. Stevens's Rooms.

THURSDAY, FEBRUARY 17.—22 cases of Araucarias, 200 cases of Japanese Lilies, Plants, Roses, &c., at J. C. Stevens's Rooms.

SELECT NOVELTIES IN SEEDS FOR 1898.
TO BE HAD FROM ALL SEEDSMEN.

BURPEE'S NEW DWARF SWEET PEA, PINK CUPID.
We call special attention to this unique Novelty of American origin. No Novelty of recent introduction has such brightness, beauty and grace combined as PINK CUPID.
Packets of 24 seeds, each 1/-; Packets of 12 seeds, each 8d.

EVERLASTING PEA, PINK BEAUTY (Lathyrus latifolius var.)
An entirely new variety, the colour of which is a delicately shaded pink on the standard, the lacing of the edge being paler than the centre, the wings are deeper pink, of a very rich shade, giving it a very striking appearance. **Per Packet, 1/-.**

PRIMULA FIMBRIATA ROSEA DELICATA.
The colour of this beautiful new variety is a charming and delicate shade of rose-pink. The flowers are large and well fringed, whilst the eye is a bright yellow, showing a striking contrast to the ground colour of the petals. **Per Packet, 3/6.**

NEW CULINARY PEA, HURST'S RELIANCE.
The finest of all second early kinds. **Per Quart, 2/-.**

NEW CULINARY PEA, CAPTAIN CUTTLE.
This superb Pea, growing about 3½ ft. high, is the result of a cross between "G. F. Wils and "Evolution." It is a most robust growing sort, and on that account should be sown thinly. The pods are large and handsome, terminating in an abrupt hook, and contain from seven to very large deep green peas of excellent quality. It is undoubtedly one of the heaviest croppers in existence. Awarded full marks of merit by the Royal Horticultural Society. In sealed Half-pint Packets, 2/6 each.

NEW CULINARY PEA, THE GLADSTONE.
In Half-pint Packets, 2/- each.

MELON, DIAMOND JUBILEE.
First Class Certificate, Scottish Horticultural Society, August 3rd, 1897.
This variety is the result of a cross between "Best of All" and "Countess," and is a d improvement on both these well-known kinds. The fruits are oblong in shape, beautiful and assume a pretty golden-yellow when ripe; weight from 3 to 5 lb., flesh greenish-white, excellent, a distinct acquisition for early crops, and will prove a boon to market growers. Per Packet, 1/6.

Wholesale only from HURST & SON, 152, HOUNDSDITCH, LONDON, E.

GREEN PEAS—JUNE TO NOVEMBER.

A correspondence was raised in the Daily Press last Autumn upon the shortness of the season when Green Peas are available, both in gardens and on the market. We now offer the following as representing the best collection selected from 1,024 rows we had under trial last season. It would be difficult for us to give precise dates for putting the seed into the ground, as so much depends upon soil and situation. Successional Sowings may be made any time between these dates, and the last sowing not later than the second week in June.

SANKEYS' famous GARDEN POTS

❊ Bulwell Potteries, Nottingham. ❊

Messrs. Dicksons, Limited, Chester, write; "The Flower Pots you have so largely supplied us with are light, strong, and well made, and in every respect highly satisfactory."

Messrs. Richard Smith & Co., Worcester, write: "We beg to say that we are highly satisfied with your 'Garden Pots.' They are well made, light, yet strong, and we like them better than any other we have ever used."

Messrs. Fisher, Son, and Sibray, Limited, Handsworth Nurseries, Sheffield, write: "We have pleasure in testifying that after having used your pots for the past twenty-five years, we have found them all that could be desired."

NATIVE GUANO.

BEST AND CHEAPEST MANURE FOR GARDEN USE.

Price **£3 10s.** per ton in bags. Lots under 10 cwt., **4s.** per cwt., 1 cwt. sample bag sent carriage paid to any station in England on receipt of P.O. for **5s.**

Extracts from 22nd annual collection of reports:—

NATIVE GUANO FOR POTATOS, VEGETABLES, &c.

C. H. TINDALL, Bardney: "Used for Potatos. Result very satisfactory; yield much above average. A splendid manure." G. WATTS and SONS, Bournemouth, report: "Good for general purposes. Grand for all Root Crops, Tomatos, and Cucumbers. Find it so cheap; and it does not exhaust the ground like other manures."

NATIVE GUANO FOR FRUIT, ROSES, TOMATOS, &c.

E. F. USHER, Sidcup: "Potatos and carrots, splendid crops; Peaches, Nectarines, &c., splendid. Should not like to be without it on any consideration." G. STONARD, Gardener to Sir A. T. Watson, Bart.: "Used for seven years for Peaches, Grapes, Tomatos, Cucumbers, Roses, and Chrysanthemums with excellent results."

Orders to the **Native Guano Co. (Limited)**, 29, New Bridge Street, Blackfriars, London, where pamphlets of testimonials, &c., may be obtained. Agents Wanted.

Cadbury's

COCOA

Absolutely Pure, therefore Best.

CADBURY'S COCOA is entirely free from all admixtures such as Kola, Malt, Hops, Alkali, etc.

PURE Cocoa is a perfect food. The Public should be wary of adulterations, and insist on having the pure, genuine article.

The LANCET says: "CADBURY'S Cocoa represents the standard of highest purity."

The MEDICAL MAGAZINE says: "CADBURY'S is, without question, the favourite Cocoa of the day. For Strength, for Purity, and for Nourishment, there is nothing superior to be found."

VEITCH'S
SUPERB
LETTUCES.

VEITCHS' PERFECT GEM
CABBAGE LETTUCE.

The best variety for summer use. A most distinct, compact-growing variety, of a rich deep green colour, forming very early a close, solid heart, beautifully crisp, juicy, and tender, and of excellent flavour.

PER PACKET, 1S. 6D.

VEITCHS' GOLDEN QUEEN
CABBAGE LETTUCE.

A small early variety of a beautiful and pleasing golden colour, literally all heart, and of a particularly delicate flavour. PER PACKET, 1S. 6D.

VEITCHS' SUPERB WHITE
COS LETTUCE.

A magnificent self-folding variety, grows to an immense size, is of superior quality, very crisp, and fine flavoured.

PER PACKET, 1S. 6D.

For full description of the above and many other CHOICE NOVELTIES and SPECIALITIES, see SEED CATALOGUE, forwarded gratis and post free on application.

SATURDAY, FEBRUARY 19, 1898.

NOTES OF THE WEEK.

A NEW ENEMY TO FRUIT CULTURE.

The action of the German authorities in prohibiting the landing at Hamburgh of American apples infested with the San José scale, has caused a flutter amongst the fruit growers on the other side of the Atlantic, and created additional interest in this terrible scourge of orchards and nurseries. It is now four years since we directed the attention of fruit growers in this country to the pest, and described its life history and its destructive effects on fruit trees upon which it effects a lodgment, and sounded a note of warning as to the risk of it being introduced to the United Kingdom. Since that time we have kept our readers fully informed with regard to the extension of its ravages in the United States. The insect derives its popular name from San José, California, to which district it was introduced from Chili, and there can be no doubt that it had been distributed over a large area before it was known to exist in the district. Since its discovery at San José, it has spread with remarkable rapidity on all sides, with the result that its ravages now extend from the Pacific seaboard to the Atlantic coast, and that an immense amount of damage has been done to orchards and nursery stock. The rapidity with which the pest has spread, and the injury that has been done, have given rise to much anxiety on the part of those engaged in the fruit industry, and considerable discussion in horticultural circles. Opinions differ in America as to whether the San José scale has been disseminated by means of the fruit or of nursery stock; but there appears to be a general agreement among those who are in a position to speak with authority, that both fruit and nursery stock have assisted in its distribution, and this view of the case has been accepted by those responsible for federal legislation for the purpose of preventing and repressing attacks. The gravity of the situation is fully appreciated in America, and no wonder, when we are informed by one of the leading authorities that the San José scale "infests all kinds of vegetation; but the chief danger is to our fruit trees and bushes, roses, and ornamental trees. It is so small as to escape observation, except by the most careful search; it is so prolific that it soon spreads over a large area, adhering to anything with which it comes in contact, and it is so difficult to exterminate that no effectual method has been found, except to burn the infested wood." We are also told that "neither heat nor cold, sunshine nor storm, has any effect upon it," and that "it infests all parts of the trunk and branches, from the crown of the root to the highest twig." This, briefly stated, is the pest with which the fruit-growing industry of this country is threatened, and yet nothing has been done by Government, by agricultural or horticultural societies, or by fruit growers or nurserymen, to obtain protection from what is admittedly a terrible scourge. American apples and pears are allowed to be imported into this country in immense quantities without regard as to whether they are infested with the scale or not. Tens of thousands of pounds are annually devoted to the maintenance of horticultural and agricultural societies in the United Kingdom, and yet not one has, so far as we are aware, lifted a finger, figuratively speaking, to protect those engaged in the production of fruit and fruit trees from so formidable a foe. It is evident those responsible for the management of these societies consider this question as of but little concern to their members, but we are strongly of the opinion that this is a case in which they should take action, and that the leading societies ought long ere this to have fully investigated the matter, and brought to the notice of the proper authorities the great risk of infestation by means of the apples and pears imported from America. We have no desire to limit the supplies of fruit, nor do we express any opinion on the question of protection as ordinarily understood, but we submit that our orchards and fruit gardens should as far as possible be protected from insect pests, and that it will be wiser to prohibit the importations of American fruit than to incur the risk of ruining what is now becoming a great and profitable industry.

ATOMS.

Although the atomic theory is accepted as a fact by our foremost scientists, it involves such a wonderful complexity of construction of matter as we know it as to be difficult of grasp by those who are unable to appreciate the higher mathematics which have led to its establishment. Nevertheless, since a little consideration of it in connection, say, with a flower, can only enhance our admiration of the creative scheme, we may do worse than devote a little time thereto. The marvels of cell construction we have repeatedly alluded to, and when we see a tiny bud gradually swelling and developing, and remember that all this is due to little bags of protoplasm which split themselves up into all the building materials requisite for the future leaves or blossoms, and carry out a most intricate plan to the utmost perfection until the leafy branch or brilliant flower is matured, we are lost in wonder at the process. The evolution of an entire plant from a tiny seed or spore, and the subsequent production of other seeds and spores, each carrying within it all the potencies of the race embedded in a microscopic germ, is still more astounding because the scope of such development is greater. As we know, in the midst of that minute germ-cell an imperceptible dot of matter has been created by the fusion of two previous ones, each containing, it may be, the potentialities of two distinct plants, and in the result this is evidenced by the characteristics of either, cropping up not merely in the immediate progeny, but possibly in the subsequent generations that it gives rise to. All this defies, to a great extent, our full comprehension, yet when we go farther still we are practically told that these minute beginnings are universes in little, composed entirely of atoms which are ever travelling about among each other, rebounding, oscillating, and moving in all directions with the utmost velocity. These atoms, moreover, diverse as matter is in character, must belong to very few elementary substances, and the possibility is by no means excluded that our present list of elements will dwindle down into one, the difference being differences of association and not of material. That extreme differences may exist in substances of exactly the same chemical composition is seen in the diamond, an intensely hard and brilliantly transparent stone, and its perfect contrast with an ordinary piece of charcoal. In these the science of atoms teaches us that the ultimate molecules are simply differently arranged, and the chemist will tell us that he can rearrange both of them differently again by burning, when the molecules, by flying farther asunder still, form an invisible gas, a third form of one and the same thing. Everything material of which we are conscious through our senses is formed of these rapidly moving atoms; in the diamond it is merely a question of shorter journeys performed by the travelling atoms, whose attraction among themselves determines the limits of the stone in the charcoal they have more liberty, and in the gas they are free to scatter themselves afar, and as the law of diffusion of gases demonstrates do so most effectually. Now with these facts in mind let us gaze upon a rose and reflect that those apparently still petals are not merely redundant with life, cell life, possibly still actively engaged in swelling the petals yet more, while others may be already building up the seed in the ovary below them; but beyond all this the flower represents a milky way, a galaxy of swiftly-moving bodies, whose numbers excel our powers of comprehension, as do those of the stars themselves in the astronomic heaven.

THE MANCHESTER ORCHID SOCIETY.

Manchester has long had the reputation of being the centre of a large and influential orchid cult, and this being so, it was natural an orchid society should be one of the results. When, therefore, the Manchester and North of England Orchid Society was instituted we considered a very proper step had been taken, and that it supplied a want, and was necessary for the progress of horticulture. We indeed felt it in the highest degree desirable, inasmuch as its committee could make awards to meritorious new and rare species, varieties, and hybrids whose owners did not feel justified in incurring the risk and inconvenience necessary to their exhibition before the Royal Horticultural Society at Westminster. We had hoped, indeed we still hope, that the Manchester Society would rise to a position beyond the anticipations of the most sanguine of its founders, by making such improvements upon the practice of the London body as time and experience might suggest. We fear, however, that our hopes will not be realised unless some of those independent and far-seeing men, for which the city is remarkable, take steps to check the tendency which has become apparent to unduly multiply awards. Knowing something of the hardheaded business capacities of the Manchester horticulturists, it was with surprise and regret that we perused the report of the recent meeting, which appears in this issue. An extensive and bright exhibition may have induced the committee to be more than usually liberal, but when certificates and awards are bestowed as freely as on this occasion, or with anything approaching the prodigality displayed, it requires no prophetic spirit to foretell that in a short time they will be regarded as of little value. It may be considered an excellent proof of the activity of the committee to broadcast seventeen first-class certificates and twenty-five awards of merit at one sitting, and it may induce some cultivators to bring forms of no particular merit to the meeting; but such action must prove injurious. We are fullly persuaded, however, that as an auxiliary or supplement to the Royal Horticultural Society there is a great future before the Manchester Orchid Society, owing to the influence it can assert over the north country, and it is this persuasion that induces us to draw attention to the recent proceedings. No useful purpose is served in granting awards to largely grown and already popular orchids, for if the work has not already been done the time for it has passed. By all means let new and rare orchids of merit be recognized, and receive distinctions that will indicate to the world at large their relative value, whether they are grown in London or in Manchester, as it is of some importance that meritorious new and little known forms should have prominent attention directed to them. Speaking broadly, when trifling variations to be found in an order of plants that is notorious for the variableness of its species are recognized, the artificial multiplication of varieties will be encouraged and the awards will lose much of the value which it is eminently desirable they should possess.

POTATO FERTILISERS FOR HEAVY SOILS.

In accordance with the policy initiated some years since, the Wilts County Council carried out during 1897 a series of experiments at Calne in the culture of potatos and some other important crops. The demonstration stations are situate at Quemerford and Lickhill, and the soil at the first-named station is very heavy, while at the latter it is somewhat light, and from the large percentage of lime it contains evidently rests on the chalk. The objects of the experiments on the heavy land at Quemerford were, so far as they related to the use of fertilisers, to show that if artificials alone be used for the potato crop, it is generally desirable that nitrogen, phosphate, and potash should all be present, to further test the value of stable manure and sulphate of ammonia used together; and to compare the effects of varying quantities of complete chemical manure, this consisting of equal weights of nitrate of soda, mineral superphosphate, and kainit. The trial ground was divided into eleven plots of four perches, and these were divided into two equal portions, one being devoted to Reading Giant and the other to Wonder. The soil of the first four plots was superior to that of the remaining plots, and it is therefore necessary to compare them with each other. The second plot, which received no manure, gave a crop at the rate of nine tons nine hundredweight per acre, and the soil therefore must have been well stored with food adapted to the requirements of the potato crop. With the application of nine pounds per perch of complete chemical manure, the yield was raised on plot four to a rate of nine tons thirteen hundredweight sixty-seven pounds, or an increase of four hundredweight sixty-seven pounds only, or not nearly enough to cover the cost of manure. Lot one received a dressing of two hundredweight per perch of stable manure, and yielded one ton nine hundredweight forty-five pounds in excess of the crop produced on the unmanured plot, the value of which excess is eleven shillings less than the cost of the manure. The heaviest crop of all was obtained on plot three by the application of one hundredweight of stable manure and three pounds of sulphate of ammonia per perch. The yield was at the rate of twelve tons seven hundredweight forty-five pounds per acre, or nearly three tons more than the crop on the unmanured plot, and taking the value of the excess at £6 15s. 3d., and the cost of manure at £4, we have a net gain of £2 15s. 3d. These results are exactly what we should have expected after a careful examination of the analysis of the soil, and they amply confirm our views with reference to the importance of so regulating the application of fertilisers as to supply the food constituents of which the soil is deficient.

Experiments with Nitragin were conducted at Calne last year under the auspices of the Wilts County Council, and more satisfactory results appear to have been obtained than at other experimental stations in England and Scotland. Nitragin consists of bacteria obtained in the first place from the nodules of leguminous plants, and subsequently increased in numbers by a process of cultivation prescribed by Professors Nobbe and Hiltner. The bacteria referred to are present in all fertile soils, and attach themselves to the roots of the growing plants, and thus lead to the formation of the nodules. When thus associated with the roots of leguminous plants, they assimilate free nitrogen from the air, and form nitrogenous compounds, which are used by their hosts for the purposes of growth. This accounts for the fact that leguminous crops are usually regarded as independent of artificial supplies of nitrogenous manures; and some idea of the amount of useful work carried on by these bacteria may be formed from the consideration that although a large quantity of nitrogen (ninety-eight pounds in an average crop of beans) is removed with the crop, the soil is left richer in nitrogen than it was before the growth of the crop. It is assumed that some soils are more or less deficient in these bacteria, and may therefore be made to bear heavy leguminous crops by applications of nitragin; and in the experiments carried out by Nobbe and Hiltner, the best results were obtained by supplying the various leguminous plants with bacteria derived from the nodules of their own particular species. At the Quemerford station nitragin was applied to the soil for winter beans, and to the seed for spring beans. The crop so treated showed no gain in the former case, but one of 4 per cent. in the latter. At Lickhill the crop experimented with was one of peas, and the nitragin was applied to the seed. There was a gain of 14 per cent. In the case of spring beans growing on a loamy soil between Lickhill and Quemerford there was a gain of 12 per cent. on the part sown with similarly treated seed.

Hop Hornbeam.—The death and consequent removal of probably the finest specimen of *Ostrya carpinifolia* in Britain, although a grafted one, has unfortunately to be recorded. It stood near the Hardy Fernery on lawn L (1) of the Kew Key-plan. For several years it had not been in good health, and on being taken down, its roots were found to have been killed by fungus mycelium. The species, which is a native of South Europe, Asia Minor, &c., was introduced to this country prior to 1724, as it is mentioned in Furber's Nursery Catalogue, published in that year. The actual measurements of the Kew tree, as given in the *Kew Bulletin*, were as follows: Height, fifty-nine feet; spread of branches, sixty-eight feet; girth of trunk, three feet from the ground, nine feet four inches. Fruit was abundantly produced, but no perfect seeds were ever developed.

Cypripediums with Fungus.—Mr. Douglas exhibited at the meeting of the Scientific Committee specimens with the roots badly infested by a mycelium. Mr. Veitch at once recognised it as the result of a too damp atmosphere, recording the fact that having on one occasion made a double roof, it caused so much damp that he lost many orchids from the same cause, but on improving the atmosphere this completely prevented any recurrence of the fungus.

Lonicera fragrantissima, the beautiful sweet-scented Chinese Honeysuckle, is now at its best in many gardens. Wherever it is grown well it cannot fail to give pleasure during February, when it produces its broad white flowers. Mr. W. Marshall, Auchinraith, Bexley, and chairman of the R.H.S. Floral Committee, has sent us a flowering branch, and his comment upon the species is that "it is one of the finest winter-flowering shrubs we have." We endorse Mr. Marshall's opinion, and state that so many fail with the plant in question because they prune it as they would most other loniceras. It should be pruned directly after flowering, because flowers are produced on wood made the previous year, and autumn or winter pruning means the loss of a crop of fragrant blossoms. Lonicera Standishi is probably but a form of L. fragrantissima, differing chiefly in the shape of the leaves.

Recent Botanical Appointments of interest are: Mr. J. G. Luchman to succeed the late Baron Ferdinand von Müller as Government botanist to Victoria; Professor O. Mattirolo, as professor of botany and director of the Botanic Gardens and Museum at Florence; and Professor F. Morini to succeed Professor Mattirolo at Bologna. We may add that a hall for the herbaria, preparations, and sections of the celebrated botanist Aldrovandi has been erected and opened at Bologna, and the cost has been met by the city and province.

Black Currant Mite.—At the recent meeting of R.H.S. Scientific Committee, Mr. Berry gave some particulars of the progress of this destructive pest in Kent. It was first observed some ten years ago, but has now reached alarming dimensions. Miss Ormerod recommended picking off and destroying the buds infested with the mite (*Phytoptus ribis*), the cause of the injury. This was done, but last year a sudden development occurred, when picking became useless. The Baldwin, a very heavy cropper, was the variety most seriously attacked. The Red Budded Naples were only slightly affected, but this variety is not a heavy cropper, and the fruit being more readily shed, it is not so useful as the Baldwin for market purposes. He suggested that experiments might be carried out at Chiswick to discover which was the most blight-resisting variety, as was done with other plants in Victoria in the Horticultural Gardens, so as to aid the fruit industry in Australia. Mr. McLachlan gave some account of the general habits of the Phytopti, remarking that this species was first noticed by Westwood some thirty years ago. It is nearly legless, and lives inside the bud, consequently it is very difficult to reach by means of insecticides. He could only recommend hand picking, unless a mite-proof variety could be found, as they had raised more or less phylloxera-proof vines. Mr. Michael also contributed further details, observing that all the species of Phytoptus were parasites, and that while many species might attack the same plant, a single species might also live on many kinds. They were excessively minute, possessing only two pairs of legs instead of eight, and always protect themselves, so that it becomes a very difficult matter to reach them, as, *e.g.*, in the curled-up edges of leaves, and within buds. It had been found that kerosene emulsion continuously applied by spraying had been more or less effective against P. pyri, but acari are far less sensitive to chemicals than insects. The eggs especially have a dense cuticle, so as to render it quite impervious to chemical action of insecticides. The only chance was to repeat the process of spraying and catch the successive broods. They only thing absolutely fatal to acarus life was boiling water; eggs and all were destroyed at once. Mr. Berry, in replying, observed that the remedy hitherto suggested of cutting down the shoots of the currant bushes attacked was quite useless. Mr. Veitch suggested that analysis of the branches of the varieties affected or otherwise might reveal some differences, but Mr. Wilks expressed himself as very doubtful of any appreciable differences being attainable even if they exist.

The United Horticultural Benefit and Provident Society has now 714 members, no less than twenty-seven having been duly proposed and elected at the recent committee meeting. Mr. George Wythes, V.M.H., Syon Gardens, has consented to take the chair at the annual meeting which will take place at the Caledonian Hotel, Adelphi, on March 14.

Diseased Pines.—Specimens of Scotch fir and of Abies Nordmanniana have been received by R.H.S. from Mrs. Marshall, Ambleside, the former attacked by the Pine beetle, the latter by Kermes abietis. This insect has always proved to be very fatal to this species of abies, and the only suggestion that could be made was to cut down the tree and burn all parts attacked. It was suggested with regard to the Pine beetle that to encourage the multiplication of insectivorous birds as far as possible might be advantageous.

Messrs. J. Carter and Co. inform us that during the recent great fire in Holborn only the outer fireproof walls of their premises were scorched, and this particular warehouse contained only a few score bales of breakfast oats; consequently orders will be executed and despatched with the usual promptitude.

The Metropolitan Public Gardens Association shows, in its fifteenth annual report, a good record of work done during the year 1897. An accompanying map indicates very clearly the work completed by the association in the metropolis, and also shows that since its institution it has carried out or successfully assisted in three hundred and sixty-eight undertakings in connection with gardens and open spaces. The successful work performed in 1897 includes the laying out of three new gardens, the provision of gymnastic apparatus for the playground, drinking fountains placed on three sites, seats placed in twelve localities, trees planted in three gardens, and assistance given in the preservation acquisition, or improvement of thirteen open spaces. The association is not above chronicling its failures, and the report states that in six instances the efforts of the body failed to secure various sites for the public use. The association is at present laying out three open spaces, and has agreed to improve four others; it will lay out, or assist in laying out, open spaces at Blackfriars, Dalston, Stratford, Hoxton, Hoxton Square, New Kent Road, Poplar, Fulham, Camberwell, and Deptford, provided their maintenance is secured. In addition to this it is seeking or assisting to secure twenty open spaces in thickly populated centres, and to secure the planting of trees in five existing gardens. The report is a perfect mine of information with respect to metropolitan open spaces. There is a list of one hundred and twenty churchyards and disused burial grounds which are already or soon will be laid out; then there is a record of two hundred and three spaces other than disused burial grounds, laid out as gardens or recreation grounds up to December, 1897; in each case the area is given, in whose possession the land is, the cost of purchase and laying out, who paid the expenses, who opened the space, and the date of opening. Other interesting remarks follow, and certainly the compilation of these lists by the association's secretary is not the least of the many good works to be placed to its credit. Some of the principal Acts of Parliament relating to Open Spaces, Preservation of Commons, &c., are added to the report as an appendix.

Cut versus Whole Potato Sets.—At Lickhill, Calne, some experiments were conducted last year by the Wilts County Council with a view to determine the relative values of cut and whole potato sets. One plot was planted with whole seed of Reading Russet, and another plot of the same size with cut sets of the same variety, the weight of seed per perch and the application of fertilisers being the same in each case. The yield from the cut seed was at the rate of seven tons five hundredweight twenty-two pounds per acre, and from the whole seed the crop was at the rate of seven tons eleven hundredweight per acre, a difference of five hundredweight ninety pounds. A similar experiment was made with Early Puritan, and resulted in a gain of one ton seven hundredweight ninety pounds from the use of whole tubers.

Shropshire Horticultural Society.—The results of the year's workings were laid before the members of this society at Shrewsbury last week, Gen. the Hon. W. H. Herbert in the chair. The financial results are eminently satisfactory, the receipts amounting to £4,517 4s. The subscriptions amount to £437 15s.; the takings at the gates on the first day £752 0s. 3d., and second day £1,825 0s. 10d. Cheap tickets to the amount of £550 were sold previous to the show. The expenditure amounted to £3,384 10s. 3d., out of which prizes, &c., were paid amounting to over £980. The profits (which, like the receipts, were the largest the society has received) amount to over £1,130. The Fruiterers' Company of London and the Veitch Memorial Trustees received hearty votes of thanks for their special prizes. T. F. Kynnersley, Esq., of Leighton Hall, was elected president for the ensuing year.

A Memoire of the Late Mons. J. Linden occupies the whole of the current issue of *La Semaine Horticole*. The issue is much larger than usual, and contains an appreciative account of the life and introductions of this able traveller, botanist, and horticulteur. Several of the principal plants introduced by the late M. J. Linden are figured, and there are three portraits of the deceased, including a reproduction from the portrait painted by M. Gaston Linden. The issue referred to is of exceptional interest, as it gives the life history of a great man, and in a large measure records the progress of horticulture during the greater part of the present century.

At the International Exhibition to be held in Paris in 1900, British industries, agriculture, horticulture, and the fine arts will be represented. To advise as to the best means of procuring and forwarding British exhibits a large and influential Royal Commission has been appointed. The commissioners are: The Prince of Wales, Duke of York, Sir F. A. Abel, Sir George Birdwood, Major-General Sir Owen Tudor Burne, Sir G. H. Chubb, Major-General Sir John Donnelly, Lord Kelvin, Sir James Kitson, Sir Trevor Lawrence, Lord Lister, Sir John Lubbock, Sir Clements Markham, Mr. W. H. Preece, Mr. E. Windsor Richards, Earl Spencer, Mr. W. T. Thiselton-Dyer, Sir E. Maunde Thompson, and Sir W. H. White.

Kew Bulletin for November last has just been published, and is devoted to the report of the Royal Commission appointed to inquire into the condition and prospects of the sugar-growing and other industries in the West Indies. From the summary of the conclusions at which the Commissioners arrived, we learn that the sugar industry in the West Indies is in danger of great reduction, which in some colonies may be equivalent, or almost equivalent, to extinction. The measures of relief suggested are the settlement of the labouring population on small areas of land as peasant proprietors, the establishment of minor agricultural industries, the encouragement of a trade in fruit with New York and London, and the grant of a loan from the Imperial Exchequer for the establishment of central factories in Barbadoes. The cost of the special remedies is estimated at £27,000 a year for ten years, the cost to be borne by the mother country; and the loan for the erection of factories is estimated at £120,000. For other purposes, an immediate grant of £90,000, and annual grants of £20,000 for five years, are recommended.

Seasons and Vegetation.—At the monthly meeting of the Royal Meteorological Society on Wednesday evening, Mr. E. Mawley, F.R.H.S., presented a report on the Phenological Observations for 1897, from which it appeared that there had been a marked absence of very exceptional weather during the past phenological year, the most noteworthy features affecting vegetation being the persistent rains in March, and the three dry periods of May, July, and October. Until about the middle of May wild plants appeared in blossom in advance of their usual time, but throughout the rest of the flowering season they were all somewhat behind their average dates in coming into bloom. The heavy rainfall in the early spring favoured the hay, which proved the only really abundant farm crop of the year. It was owing more to the dry spring and summer, and the sunless autumn of the previous year, than to the moderate frosts and cold winds of the spring of 1897, that the fruit crop was such a very light one. Apples, pears, and plums, and especially the latter, yielded badly; while the small fruits were in most districts only an average crops.

Early Spring Flowers.—Our coadjutor "H. H. D.," writes: It seems almost difficult to write about the opening spring when we have had no winter, for without any frost worth speaking of and without hardly a flake of snow, with high barometric readings and sunshiny days, it is very hard to imagine that we have passed through the cold months of December and January without feeling the usual inconvenience resulting from dark and dreary and cold days and bitter nights, and so now on St. Valentine's Day we are rejoicing in the continual putting forth of the blooms of our old favourites. For instance, I am greatly delighting in a piece of colouring in my front rockery; this is alongside of the drive leading up to the house, thoroughly exposed to the south, and sheltered from the north by the shrubbery and trees. It was here that some years ago I placed a few bulbs of the hardy cyclamen, either Coum or Atkinsi. I failed with them in other parts of my garden, and having read somewhere that they rejoiced in such a situation, I placed them here. The results exceeded all my expectations; not only have the bulbs greatly increased in size, but they have seeded all over this part of the rockery, which now for several square yards is full of them, their beautiful marbled leaves and pretty flowers of various hues of colour affording a rich treat to the eye. Associated with them is a quantity of aconite, with its bright yellow flowers, snowdrops, and a few crocus, the whole forming a very pretty picture. I believe the success of the cyclamen is due to the very sheltered and sunny position which it enjoys. The corms are thoroughly baked in the summer, and I believe that this is the one great element of success for many bulbs; I am sure it is with freesias when grown in pots, and I do not think that daffodils ever do so well when there is heavy rain at the time of their ripening off; and I am quite sure that if any one has had difficulties (as I know many have) with the hardy cyclamens, they may ensure success if they can find a spot in their gardens something similar to that I have now mentioned.

Mr. Charles Mason, surveyor to the vestry of St. Martin's-in-the-Fields, has become a partner in the old-established business of Messrs. Foster and Pearson, horticultural builders and heating engineers, of Beeston, Notts. Mr. Mason's resignation was accepted with much regret at the recent meeting of the vestry.

Sanctuaries for Birds.—In an interesting communication on the increasing scarcity of rare birds, in the current issue of *Nature Notes*, Mrs. Brightwen states that she cannot see how their destruction is to be prevented unless landowners can be induced to make their estates, in some measure at least, sanctuaries for such of the feathered tribe as are scarce and interesting. For the last twenty-five years on her place there has been no shooting, save to keep down rabbits, and this is the result: Although it is of small extent, only comprising a hundred and seventy acres, and situated within eleven miles of London, the fields and woods are fully tenanted by several kinds of owls and hawks, the green and greater spotted woodpeckers, nightjars, lapwings, and a great variety of the smaller species of birds. Nuthatches abound; we have five species of titmice, gold crests, blackcaps, tree-creepers, and nightingales. The woodcock is sometimes seen in the spinney, and snipe, both in the running water of the park and along the edge of the wheat-fields. There is no lack of warblers and finches to make the woods vocal in spring and summer. This Mrs. Brightwen very justly claims to be a highly satisfactory result of protective care. In reply to the petition of the Guildford Natural History Society, praying for the preservation of Wolmer Forest as a sanctuary for wild birds, thus constituting a national memorial of Gilbert White, of Selborne, the Marquess of Lansdowne states that, while he is fully in sympathy with the aims of the memorialists, he considers the continuance of the system now in force would, so far as it is in the power of the War Department, best promote the objects of the society. Enclosed with the reply was a copy of a report made by Captain A. H. Cowie, R.E., who has had the Government ground in question under his management since 1895. In this report it is stated that since that year all birds had been strictly protected. No birds, except game birds, had been allowed to be shot. All hawks, owls, and other birds had been carefully preserved, as far as possible. The heronry had gradually increased from one nest a few years ago, to about twenty nests now, and nearly fifty young herons flew from the nests in 1897.

Cannes Battle of Flowers, the other day, was held under eminently favourable climatic conditions. The weather was perfect, the carriages were for the most part decorated with much taste, and the beautiful sea drive was lined with upwards of twenty-five thousand persons. It is computed that about ten tons of flowers were used in the battle, these consisting chiefly of acacia, anemones, pinks, violets, and wallflowers.

The Kew Guild annual general meeting is to be held on the 24th inst. in the Lecture-Room at the Royal Gardens. Eight o'clock is the time of meeting, and the entrance will be by the Melon Yard Gate.

A MORNING MIXTURE.

Diluculo surgere saluberrimum est.

THINGS are a little quiet just now. The fact itself is not particularly surprising, but the reason for it is, namely, that owing to the openness of the season work has got so far forward as to permit of a lull. Still, there is something in the air. I do not know what it is, but it is there. I got into the midst of an uncompromising gardening circle the other day, and felt it without a word being said. Remarking on the electrical undercurrent to one of the party, he responded with a portentous "Ah!" and an air of profound sagacity, which said as plainly as words could that he held a secret of terrific importance locked within his breast, and could spring it on a startled world if he liked.

Now, the deduction which I drew was that if I were to exert myself a little I could get behind the scenes and find out all about it. But it so happens that "getting behind the scenes" is one of those things which I have an inveterate objection to. Please do not imagine from this that I am elevating a superior nose, and proclaiming a supercilious immunity from such human frailties as curiosity. I am simply stating a fact which is based on sound business principles. Nine times out of ten, when some individual puts his finger on his lip and leads you round a back entry it is only to tell you some trivial, tinpot thing, for the knowledge of which you are not a whit the wealthier or the wiser. It is nice in a way to feed the flattering delusion that you are one of the elect, that you are "in the know," and so on; but when you perceive that other people who are not of the elect, and who are transparently out of the know, get on quite as well as you do, if not rather better, you begin to perceive that time spent behind the scenes is of doubtful value, and to wonder how much better off you are for all these tremendous secrets. For my part, anyway, I have come to the conclusion that it doesn't pay, and even that tempting word "plot" fails to draw me. My experience is that the commonest feature of a plot is that it never comes to anything.

The only sort of plot I ever mean to have anything to do with is that in which I am sole instigator and perpetrator; then I can comfortably regulate the running away. There is always pleasure in a fight when you know you can bolt without anyone being the wiser. For the moment, however, I do not wish to contemplate any such pusillanimous proceeding; on the contrary, I feel impelled to liven up the prevailing dulness by respectfully offering to accept battle from anybody on any subject I am prepared, be it understood, to sacrifice myself simply for the entertainment of readers. In pursuance of this praiseworthy resolve, I turn my eyes round in search of the old fighters. Will Mr. J. Riddell step out and tweak my beard? He thumps as hard as anyone when in the humour. Perhaps, too, "A. D.," that sound old warrior, will, in Shakespearean parlance, bite his thumb at me, and move me to wrath. Could the latter, I wonder, have had one eye on me when he penned that note about Chiswick as a school garden? The whole trend of it is in favour of practical teaching, which, of course, can only be properly tested by practical examinations, but "A. D." still holds coyly aloof from the latter. I am not going to dwell on this topic, because experience has mournfully convinced me that, however numerous the supporters of the present examining system may be, they do not screw their courage up to fighting point.

I am keeping a watchful and jealous eye on the chrysanthemum specialists. I know the objects they have in view well enough. They mean to lengthen the season if they can, apparently oblivious that the chrysanthemum owes its enormous popularity to the fact that it is the flower of one particular season. Past indulgence from Mr. Lees prevents my attacking him for worrying us about early border chrysanthemums in February, and naming dozens of varieties for September and October flowering; but, all the same, our good understanding is severely strained. I do not believe the public want chrysanthemums before October at the earliest, and what the public don't want will not get on very fast. The best of the very early sorts are but poor things compared with Michaelmas daisies for autumn effect in the garden, and a great deal of the praise which the specialists heap upon them is hackneyed, forced, and overstrained. The man who teaches flower-lovers the best sorts of perennial asters, and the way to make the most of them, will have more of my sympathy than he who bothers us with early chrysanthemums. They as tiresome as the Crummles phenomenon.

Our peach critics are at it again. First it was Mr. Cook, and now it is Mr. Molyneux. What these excellent gentlemen say is right in its way, but no amount of quibbling about coping, pruning, or fly killing will do away with the fact that the peach is indubitably a more tender tree than the apple, pear, plum, &c. Look over large nursery quarters after a severe frost, and the true lesson of the general non-success of peaches out of doors will be learned at a glance. Of course, it is open to anyone to argue about more or less important details, and there can be nothing but praise for the spread of some cultural information, but broad principles must be recognised. One of the most amusing things in connexion with outdoor peach growing is the calm assumption of its superiority in days gone by. This is invariably accepted as an incontrovertible fact, but singularly enough, such proof of it as has been forthcoming hitherto has consisted principally of significant head-nodding on the part of those who have caught the habit off somebody else. As one who can dip back further into the past than many of my readers, I should like to express my conviction that the vastly superior level of outdoor peach culture in days gone by is very much of a myth.

A remark as to early potatos in Mr. H. C. Prinsep s calendarial notes makes a man rub his eyes. The sets, he tells us, should by this be placed on their ends. There is a quaint and delicious Rip van Winkleism about the advice which seems to suggest that the worthy writer has not been on end himself of late, but has been enjoying a quiet nap. If the phrase "by this" means, as it may be fairly assumed to do, "now," then I beg to say that the Luxian potatos have been on end for many a week, and are, as they will remain till wanted, in prime condition for planting. Happily, Peter is a calendar unto himself. That great authority on practical horticulture does not believe in leaving his early potatos till winter is half over before up-ending them, and I verily believe that if anyone ventured to suggest it to him he would lay the unhappy adviser low. Another subject on which he has strong opinions is the size of the sets. Peter clings tenaciously to the old partiality for small seed. Two ounce seed is the most he will allow himself, and he only takes that under protest. I am now preparing a bitter pill for him. Well aware that he will accept nothing experimental, I am procuring the experience of successful potato exhibitors. So far the result is against him, but perhaps others will take his side. Now, Mr. Beckett?

LUX.

METHODS AT FLOWER SHOWS.

THE editorial note on page 29 will find many supporters I am quite sure, for the methods alluded to are still adopted at some shows, and appear likely there to last. My experience of exhibitions, and especially those held in the autumn in different parts of the United Kingdom, leads me to say that officials are less suspicious than formerly of collusion between judges and exhibitors. If those who are so suspicious knew what it was to have a reputation to sustain they would perhaps cease their suspicious methods. Judges, as a body, much prefer not to know whose exhibits they are examining, but; in spite of all secrecy regarding the numbering of classes and so forth, judges sometimes do know the exhibits they are examining. I very often feel quite sure who the chrysanthemums belong to that I am called to adjudicate upon; especially is this the case when dealing with incurved blooms. The "style" and "finish" of the blooms is distinctly that of Mr. So-and-So. Surely, then, to an honest mind, this cannot make the slightest difference. Judges, as a rule, prize a second or a continued annual invite more than an invitation from a fresh society. The fact of their being again asked to judge is a sufficient proof of what that particular society thinks of them as judges. As an old exhibitor, I appreciate the method of publishing the judges' names in the schedule; such a plan is more likely to encourage competition than lessen it. As an exhibitor, also, I prefer some judges to others, thinking that some are more painstaking than the rest. Some judges are in too great a hurry at times to well weigh all the details in close competition; but perhaps such men are no more liable to make mistakes than those who spend double the time over one particular class. Still, in my opinion, sufficient time should be given to the work to examine all details thoroughly. To a judge, the method of having numbers simply on small cards, or numbers on the reverse side of prize-cards, as a guide to the classes, is of no consequence; but to the secretary and his assistants it is of vital consequence, and to the public also it is at times most important.

The method of affixing the value of the prize by adhesive slips on previously written cards may be a trifle more expensive, but it certainly is the most efficient method to all concerned, and I am pleased to see the rate of progress the plan is making. Under this system, directly the awards are made, the press and the public, if then admitted to the building, are cognisant of the prizetakers. I am positive that I have never seen an officiating colleague turn over a card for the purpose of knowing who the exhibitor was until after the award had been made. Some societies use in the place of adhesive slips rubber stamps for denoting the quality of the prize. This is a capital plan, not only quick, but effective. The "Field" judging-books, containing a counterfoil leaf, are very often employed, and they no doubt facilitate the work of the clerks in booking up the awards for catalogue printing, or for an early publication of the prize list, which so many like to have, but as far as I can see it does not facilitate the setting up of the prize cards for the benefit of reporters and the public. The secretary is wise who requires the judges to write on the back of the card the value of the prize as a reference, in case of an error or dispute afterwards. It sometimes happens that the prize cards are moved, and a reference then to the back of each very often puts things right again, in the case of a mistake occurring.

The greatest mistake that secretaries make is that of allowing [illegible] much latitude to exhibitors on the morning of the show. Many secretaries are far too lax in this, and exhibitors are not slow to take advantage of their relaxation. Too often the judges have not sufficient time allowed them to give that consideration they would personally prefer to [illegible] close in order of merit, simply because a good hour of their allotted [illegible] has been frittered away through non-compliance with the rules by exhibitors, encouraged by lax officials. It is difficult and invidious to [illegible] selection of those who err in this and those who do not, but I [illegible] refrain from mentioning the executive officers at the autumn show [illegible] Hull. Mr. Dixon can yearly be found in front of the clock two minutes to ten on the opening morning of the show, with the bell in hand, ready to sound the clearing out note. I never yet heard a grumble there [illegible] a single exhibitor about the hardships of the rule. Exhibitors know [illegible] to do, and they do it, and so they would everywhere if it were made [illegible] pulsory. Perhaps these few well-intentioned remarks on this detail [illegible] be carefully read and digested by those who are admittedly somewhat [illegible] easy about clearing the show room at the appointed hour.

Swanmore Park Gardens. EDWIN MOLYNEUX.

Annual Rose.—Carter's Annual rose is not only a gem as a pot plant, but it makes a lovely bed if planted over a groundwork of blue lobelia and edged with yellow pyrethrum. It is easily raised in a cold frame, and will [illegible] flower when only a few inches high. The flowers are both double and [illegible] all shades from rose to pure white.—JOHN APLIN.

THE PARENTAGE OF ROSES.

THE subject of this article must always be a peculiarly fascinating one to rose cultivators, many of whom, doubtless, find it very interesting to grow such varieties as Souvenir d'un Ami and Souvenir de S. A. Prince, Catherine Mermet and The Bride, the parent and the offspring, side by side. In this way they may have many valuable opportunities of observing the influence of the law of variation. In most instances it will be found that the difference consists almost solely in the colour, the other important attributes of growth, habit and formation remaining the same. The Bride, for example, with the exception I have indicated, has the self-same characteristics as the notable variety from which it was derived; it has even below the petals the same exquisite suggestion of delicate green, reminding one instinctively of the aspect of a celebrated lily, L. speciosum Krætzeri, whose beauty is of a similarly distinctive description. The variation from Souvenir d'un Ami, discovered at Oxford by that great rosarian the late Mr. George Prince, has the charming fragrance and floriferousness of its parent, but the pale pink of the one has become in the other a precious pure white hue. This, in my opinion, is by far the most valuable of all tea roses of its special colour, at least for garden cultivation. It has more vigour, finer foliage, and opens with greater facility than The Bride; but I consider the latter the more perfect variety when adequately grown. Souvenir de S. A. Prince is, however, a much more accommodating and reliable rose; if inferior in form, its perfume is more attractive, and of a widely different kind; if, therefore, The Bride has any superiority, it is found in the beauty of the individual flowers. Niphetos is an old favourite, of whose origin I know nothing, but though it may be admitted that the climbing form is much less capricious than the original variety, I do not find it so worthy of praise as either of its rivals in the essential matter of artistic formation. Even when grown on a sheltered south wall, it often has a ragged and imperfect ppearance.

Many of the older roses, whose names are historical, but whose aspect and attributes are, to the present generation of cultivators, almost unknown, now exist for the most part only in their descendants, some of which, therefore, it may be presumed, are more generously endowed. La Reine, for example, of which in his day the late M. Laffay was especially proud, lives on in François Michelon, Paul Neyron, and that more refined derivation from the latter entitled Ulrich Brunner, of German origin [?]; whose value, I greatly fear, has been somewhat overestimated, probably because Teutonic roses of eminence are so rare; while another of the floral children of La Reine, Auguste Mie, on the principle that "the weakest '—perhaps not in vigour—" goes to the wall" (though generally the strongest roses go there!), has been relegated by British rosarians to oblivion. Most of those varieties which drew their individuality from the brilliantly-hued "Giant of Battles" (Nerard, 1846), have disappeared from our most conservative and comprehensive collections, an outstanding exception being Cranston's Crimson Bedder, which, by reason of its bright colour, its rich fragrance, and productiveness, should be much more extensively cultivated than it is. Some of the grandest crimson roses, such as Duke of Edinburgh, Duke of Albany, and Charles Lefebvre, are deficient in the quality and strength of their perfume, nor are they too effusive of their lustrous flowers; it is, on the other hand, in those special and by no means unimportant directions that the less perfectly finished Crimson Bedder is supreme. There is at least one grand old hybrid perpetual that is still discoverable, not only in our catalogues, but also growing and flowering very effectively in our gardens. I mean the veteran-like General Jacqueminot, a rose that survives by reason of its beauty, its free-flowering qualifications, and strong constitution. It has many highly distinguished descendants; among which some of the most impressive are Charles Lefebvre, Duke of Edinburgh, Senateur Vaisse, Alfred Colomb, and Prince Camille de Rohan. Perhaps the finest existing derivation from Jules Margottin is Beauty of Waltham, still highly popular with amateurs, and even with exhibitors; a native of Waltham Cross. It is a rose of great sweetness, and, like Tennyson's Warrior in "The Princess," "worthy to be loved." Roses in this respect much resemble human beings; some of them are more admirable than lovable, because, though commanding in their dimensions, they are not sweet, such, for example, are Baroness Rothschild and Merveille de Lyon. It is a kind of soulless beauty, if I may so express it, that exists in these. None of the varieties which have been derived from Charles Lefebvre, with the exception, perhaps, of Horace Vernet (which seems to be utterly lacking in vigour and vitality), sustain the reputation of the parent rose. Mrs. Harry Turner, which owns, presumably, the same origin, but not an equal perfection of form, though somewhat deficient in central petals, is a radiantly-beautiful garden rose.

The special varieties which have drawn their attributes from Baroness Rothschild, most of which possess an unsatisfactory pale, pinky-white [illegible], are White Baroness, Mabel Morrison, and Merveille de Lyon. Of these the last mentioned is often described as "our finest existing white hybrid perpetual," probably because it has no serious rivals in renown. Nevertheless, it has considerable limitations; and its trans[illegible] aspect is by no means edifying, after its petals have experienced a heavy shower of rain. A much more beautiful and valuable rose is Gloire Lyonnaise; but the finer qualities of its nature have been inherited from the teas. Duke of Edinburgh, like the Baroness Rothschild, has been prolific; but none of its variations, not even the luminous Duke of Teck, is equal to itself. I have seen Sultan of Zanzibar occasionally impressive; also on several occasions in my garden the dark, marone-shaded Reynolds Hole; but the Dean of Rochester, whose name it bears, has described it as being very uncertain, and experience has told me that his description is correct. Among roses of considerably more recent origin, Duke and Duchess of Fife have drawn their best features from Etienne Levet and Countess of Rosebery, having originated at Aberdeen with the Messrs. Cocker, who are eminent as rosarians and cultivators of herbaceous flowers. They have also given us a very handsome rose for the garden in Duchess of York, whose colour is identical with that of Maiden's Blush. Mrs. Harkness is derived from Heinrich Schultheis; Margaret Dickson, a nobly endowed variety, from Lady Mary Fitzwilliam and Merveille de Lyon; while the former hybrid tea, in conjunction with La France, has given us Mrs. W. J. Grant, which is very beautiful in bud, but not equal to its parents at any subsequent stage.

Some of the older noisettes (whose name is *not* legion) are still in cultivation; among these is Aimée Vibert, and Lamarque (Maréchal, 1830), the parent of Cloth of Gold, and great grandparent of Maréchal Niel. Its hue is very pale yellow, approximating to white, which makes it somewhat hard to understand why the heirs of its attributes (including considerable tenderness and consequent unreliability) should have been so much deeper and more effective in colour. Gloire de Dijon, which always reminds me of a very short and stout lady, with a most amiable expression, has some daughters of a more refined formation, of which perhaps the finest are Boule d'Or and Belle Lyonnaise. One of the most graceful of recent introductions is Fiametta Nabonnand. I have been much interested to learn that this rose is the result of a cross between Niphetos and Papa Gontier, and partaking to some appreciable extent of the characteristics of both. It would be even more interesting to ascertain the origin of that uniquely coloured variety Empress Alexandra of Russia, which is likely to prove a formidable rival of Comtesse de Nadaillac and Madame Lambard. It is much more easily cultivated than the former, and surpasses the latter in artistic fascination.

Kirkmaiden. DAVID R. WILLIAMSON.

GRASSES.

NOTWITHSTANDING the vast areas of the earth's surface which are densely clothed with forest growth, wherein the grasses are in the minority, in one or other of their forms, minute or gigantic, they probably cover by far the greatest portion. Except in the most arid deserts, some species or other always manages to find a foothold, and although in the dry seasons of the tropics the traveller, regarding the parched-up prospect, and even curiously examining the rocks and soil around him, might be inclined to deny the existence of any vegetation whatever, a few days after the rains have set in every chink and cranny reveals the contrary, and the blades of the all but ubiquitous grass speedily transform the seemingly barren scene into a verdant and fruitful one. It is probable, too, that, having regard, as it were, to the versatility of the grass family, as well as to the abundance of its members, no other tribe can rival it in its general utility to man.

We can roughly split it into three classes: first, those numerous species which, in all parts of the world, do their best to monopolise the soil wherever there is a suspicion of moisture, and the nutritious nature of which constitutes them the first of forage plants, so that indirectly we owe our cattle, sheep, and horses, and their myriad bye-products, so to speak—meat, wool, leather, and so on—to this branch of the grasses; secondly, we have those which, by man's selection, and under his careful cultivation, yield our daily bread in all its forms from their highly-developed seeds—maize, wheat, oats, barley, &c.—again all due to grasses, so that the old adage, "All flesh is grass," is extremely near the mark, though other fruits of the earth yield a fair contribution in these later days of varied foods. Then, if we go to warmer climes, we find some members of the selfsame tribe know how to profit by the solar heat and terresrial moisture; and lo! the bamboos—like grass under the microscope—soaring up for scores of feet, and yielding, from jointed stalk and leafy blade, endless utilities to the deft hands of the natives, their lithe, cylindrical shafts, hard as steel almost, varnished by Nature, and only needing cutting and joining, splitting and splicing, in the most primitive fashion to provide house furniture, and tackle of all sorts—again all made of grass. Another tribe of the giant persuasion adds sugar to our list, each knot a lollipop, the annual crop the outcome of a mighty industry.

It is indeed curious that in so extremely varied and widespread a family one and all appear to be at once innocuous and useful. In other tribes evolution, in some mystic fashion, has often linked deadly poisons closely together with nutritious foods, even, it may be, in one and the same plant or fruit—examples, the peach and almond, bearing the deadly prussic acid in their kernels, while the deadly nightshade and the delicious tomato or mealiest potato are very close relatives, as their flowers betray, though woe to the cook who made a general salad of the lot, as the cow does in the pasture with its various grasses. Our stately oak has its poisonous cousin in the States, and in the manifold forms of the other great division of dicotyledons boon and bane go hand in hand in very many instances. In the grasses, however, wherever grass grows, no matter the species, cattle may feed with impunity, and in the various grains we find, and naturally expect, the like, as they are all the result of selection. Considering the great likeness which runs throughout the tribe, so that in their very young state, except as regards size, seedlings are almost indistinguishable the one from the other, it is a great blessing that hay fever appears to be the only ailment to which humanity seems subject through its acquaintance with the grasses. C. T. DRUERY, F.L.S.

Transplanting Onions.—As the writer of "Men and Methods" at page 83 refers to diverse methods of transplanting winter-raised onion plants. I may mention that transplanting from the boxes into which they are pricked from the seed boxes with balls of soil, so that the roots are quite undisturbed, is the regular practice of Mr. Bowerman, gardener at Hackwood Park, Basingstoke, who has for two or three years been the champion grower, having always had the finest bulbs. Now, the grower who washes the soil from the roots of his plants before he plants outdoors may be able to show prize cards, &c.; but in what sort of competition? Another gardener, who is a first-class vegetable exhibitor and invariably has fine onions, is yet with these bulbs always beaten by Mr. Bowerman, but the other washes all soil from his plants before transplanting. Seeing what splendid results come from the balls of soil, is it not the best way?—A. D.

IN THE ORCHARD.

THE winter so far has proved one of the most favourable on record for carrying on all kinds of work in connexion with fruit growing, particularly in orchards. Since the fall of the leaf there has been nothing to interfere with lifting, root-pruning, and planting, and all such work should be in a forward state generally. At any rate, where it is not so, the plea of adverse climatic conditions cannot well be advanced as the reason for arrears. Root-pruning is always best done before the turn of the year, and the same remark applies to root-lifting, as the trees do not then sustain so severe a check from the performance of the operation. Any trees which may be needing a check should therefore be attended to at once, and the work brought to a conclusion as early as possible. Turning next to planting. This has been carried out from early autumn up to the present time with most favourable results as regards the working of the soil. The latter has invariably broken down well, and there has been no difficulty in obtaining a sufficiency of the finer particles for working amongst and covering the roots. Trees planted under such circumstances should, and will, no doubt, succeed, and growers may look forward to the result with equanimity.

There yet remain another few weeks in which planting may be done, and although no advocate for late planting of fruit trees, especially for orchards, I should not hesitate in the matter if time is an object, and there are many gaps to make good, or a fresh area to plant up. The great thing to observe in this case is to keep the roots of the trees out of the ground as short a time as possible, and to well moisten them in "puddle" composed of clay and water before planting. Ordinary soil will do in case clay is not procurable, and a little cow manure added will render the "puddle" more adhesive. This clings to the roots and keeps them uniformly moist until new roots are emitted and push out into the soil surrounding them. Staking is a matter which has a great deal to do with their future success or otherwise, as, if not kept firm and rigid, trees never do any good. When improperly staked they are at the mercy of the wind, which, in swaying them backwards and forwards, causes a funnel-shaped hole to be worked out round the stem, extending from the surface of the soil down to the roots. Every time rain falls the water pours down this opening, the roots become water-logged, they soon begin to decay, and in course of time—unless the matter is remedied—the tree dies.

Matters calling for attention at the present time where all the foregoing details have been carried out, are the pruning and cleansing of the trees, and manuring or top-dressing all such as need it. These, it may be mentioned, are operations which are too often observed in the breach, which is to be greatly deplored, as it is owing to such neglect that many orchards are in their present miserable condition. When the trees in an orchard have arrived at a bad state for want of pruning and the keeping down of insect pests, it takes a long time to bring them back to a healthy condition again. As regards pruning, this has to be done by degrees, as the adoption of too severe measures at the outset practically ruins the trees. Very often the cutting out of the dead wood alone in such cases suffices for the first year, as this alone exposes the remainder of the wood on the tree to more sunlight and air than it has experienced perhaps for years. The following season a general thinning of the heads may be done by cutting away branches that cross each other, and by a judicious reduction of the spray at the ends of the branches retained, so that sunlight and air may penetrate freely to all parts of the tree. The removal of large branches should be carefully avoided in such cases of neglect, as this invariably gives the trees a shock from which they seldom recover. Well-managed trees require but a general examination every year, which will keep them in good order and in a healthy, bearing condition.

With regard to parasites, such as moss, lichen, and mistletoe, these should be got rid of at all costs. The first two may be killed by whitewashing the stems and branches, and by syringing the self-same wash after straining it through a fine sieve among the smaller branches and sprays. Another good plan is to cast freshly slaked lime freely all over the trees directly after rain or during a fog when the wood is moist. This adheres wherever it touches, and quickly does its work, and may be repeated if the first application should be washed off. Those possessing appliances in the shape of hopwashers of the manual or horse-power type could not put them to a better use at this time of the year than to wash their orchards with them, either with the simple mixture mentioned above, or the more sure and effective remedy, made of caustic soda and potash. For a hopwashing machine, the limewash should be first strained through an old bag, and then thoroughly wet every part of the trees with the mixture. A manual machine would be the best to apply the soda and potash solution with, and the end of the branch pipe should be fitted with a sprayer. For tall trees, two or three lengths of galvanised tubing, made to screw into each other, are needed, so that the topmost part of the tree shall be effectually reached with the spray. These lengths can be fitted together as required by the person applying the wash, and the branch with the sprayer at the end should be made to fit any of these. This solution is made by boiling one pound of caustic soda and one pound of crude potash together in ten gallons of water. This will serve as a basis of calculation when large quantities are required. This kills all insect life, chrysalids, and eggs, as well as parasites, but must not be applied afrer the buds become prominent.

As regards manuring and top-dressing, a good dressing of farmyard manure spread over the surface of the ground under the trees acts as a good stimulant when they merely require something to keep them up to their work. If lacking energy, something more than this is needed, and if the orchard is a grass one, the sward beneath each tree should first be removed. Then apply the manure, after lightly pricking up the soil lying over the roots, or, if the manure cannot be spared, apply bone-meal, or bone-meal and kainit mixed with wood ashes sufficient to colour the surface of the soil. Dried blood and bone-meal, mixed in equal quantities make a good stimulant, as does fish manure, and superphosphate of lime and muriate of potash. The two latter chemicals must be mixed together in equal quantities and applied but sparingly, as they [illegible] powerful stimulant. Two ounces to a square yard is a sufficient dose [illegible] this at any one time. After spreading or sowing the manure, return the turf, not necessarily in the turves as dug up, but chop them up, and [illegible] the pieces grass side downwards as far as possible, and tread all firm again. Liquid manure is also valuable, and this may be carted and applied to the surface any time during the winter months. The more moisture [illegible] soil contains the more valuable will the liquid prove, as its fertilising properties will be arrested and stored up for future use, instead of passing on down to the subsoil and be lost, as it would do if the soil be dry. This is also an excellent way of disposing of the contents of cesspools and sewage tanks. The liquid can be used in the way described, and the solids, when mixed with coal ashes or fine soil, can, when quite dry, be used as a top-dressing. All the above-mentioned manures, whether liquid or solid, can be applied with equally as good results to trees growing on arable land as on grass land. Whatever stimulant is given fruit trees on arable land should either be lightly dug in beneath the trees or buried; first remove about three inches in depth of the surface soil, then, after spreading or sowing the manure, return it, and make all firm again by trampling it a few times.

Stoke Edith Gardens. A. WARD.

LÆLIA ANCEPS WADDONIENSIS.

IN all its varied forms Lælia anceps is a most beautiful and acceptable winter-flowering orchid, not very difficult to manage and amply repaying during its period of inflorescence for all the trouble expended upon it during the rest of the year. The brightly-coloured forms are by far the most common, and some of these, such as L. anceps Barkeriana, L. a. Crawshayana, L. a. Scottiana, L. a. Chamberlainiana, L. a. Ballantini, &c., are wonderfully rich, large, and beautiful. Then there is a section with paler colouring, sometimes a quite delicate shading over a white ground; these are extremely elegant, and include such gems as L. a. Amesiana, L. a. blanda, L. a. delicata, L. a. Keinastiana, L. a. leucosticta, L. a. Percivaliana, L. a. rosea, and L. a. Veitchiana, &c. Then we have the white varieties, and possibly the greatest interest centres in these, while on the score of beauty and elegance they certainly cannot be beaten. First among these with regard to purity comes L. a. alba, which has a pale yellow disk, but no markings on the inner surface of the side lobes. In point of extreme beauty combined with size and fine formation L. a. Schröderiana stands first, though in breadth of petals it is probably beaten by L. a. Dawsoni. Following these come the lovely varieties of L. a. Sanderiana, L. a. Ashworthiana, L. a. Hilli, L. a. Stella, L. a. vestalis, L. a. Williamsiana, and the new L. a. Waddoniensis.

The latter variety first made its appearance at the Royal Horticultural Society on the 8th inst. It came from the gardens of Philip Crowley, Esq., F.L.S., Waddon House, Croydon, and was staged by his gardener, Mr. Harris. It is a remarkably fine form, and will no doubt improve, for the two spikes shown each bore but two flowers. The two largest flowers measured a little more than four and a quarter inches across, while from the apex of the lip to the tip of the dorsal sepal measured fully four inches. The broad petals and narrower petals are of great substance, pure white throughout, save for a faint tinge of green at the tips of the sepals in a newly-opened bloom. The lip is notable by reason of its broad, bold front lobe, which is pure white; the disk is very thick, and of a rich golden yellow colour. The side lobes of the lip are white, but along the inside are veined with pale purple, the veins shading to crimson-purple as they recede. L. anceps Waddoniensis has somewhat small pseudo-bulbs. Altogether it is a very fine orchid, and if it scarcely comes up to the high standard of L. a. Schröderiana, it is nevertheless well worthy to represent the white varieties of the species in the collection of the genial Treasurer of the Royal Horticultural Society. C. K.

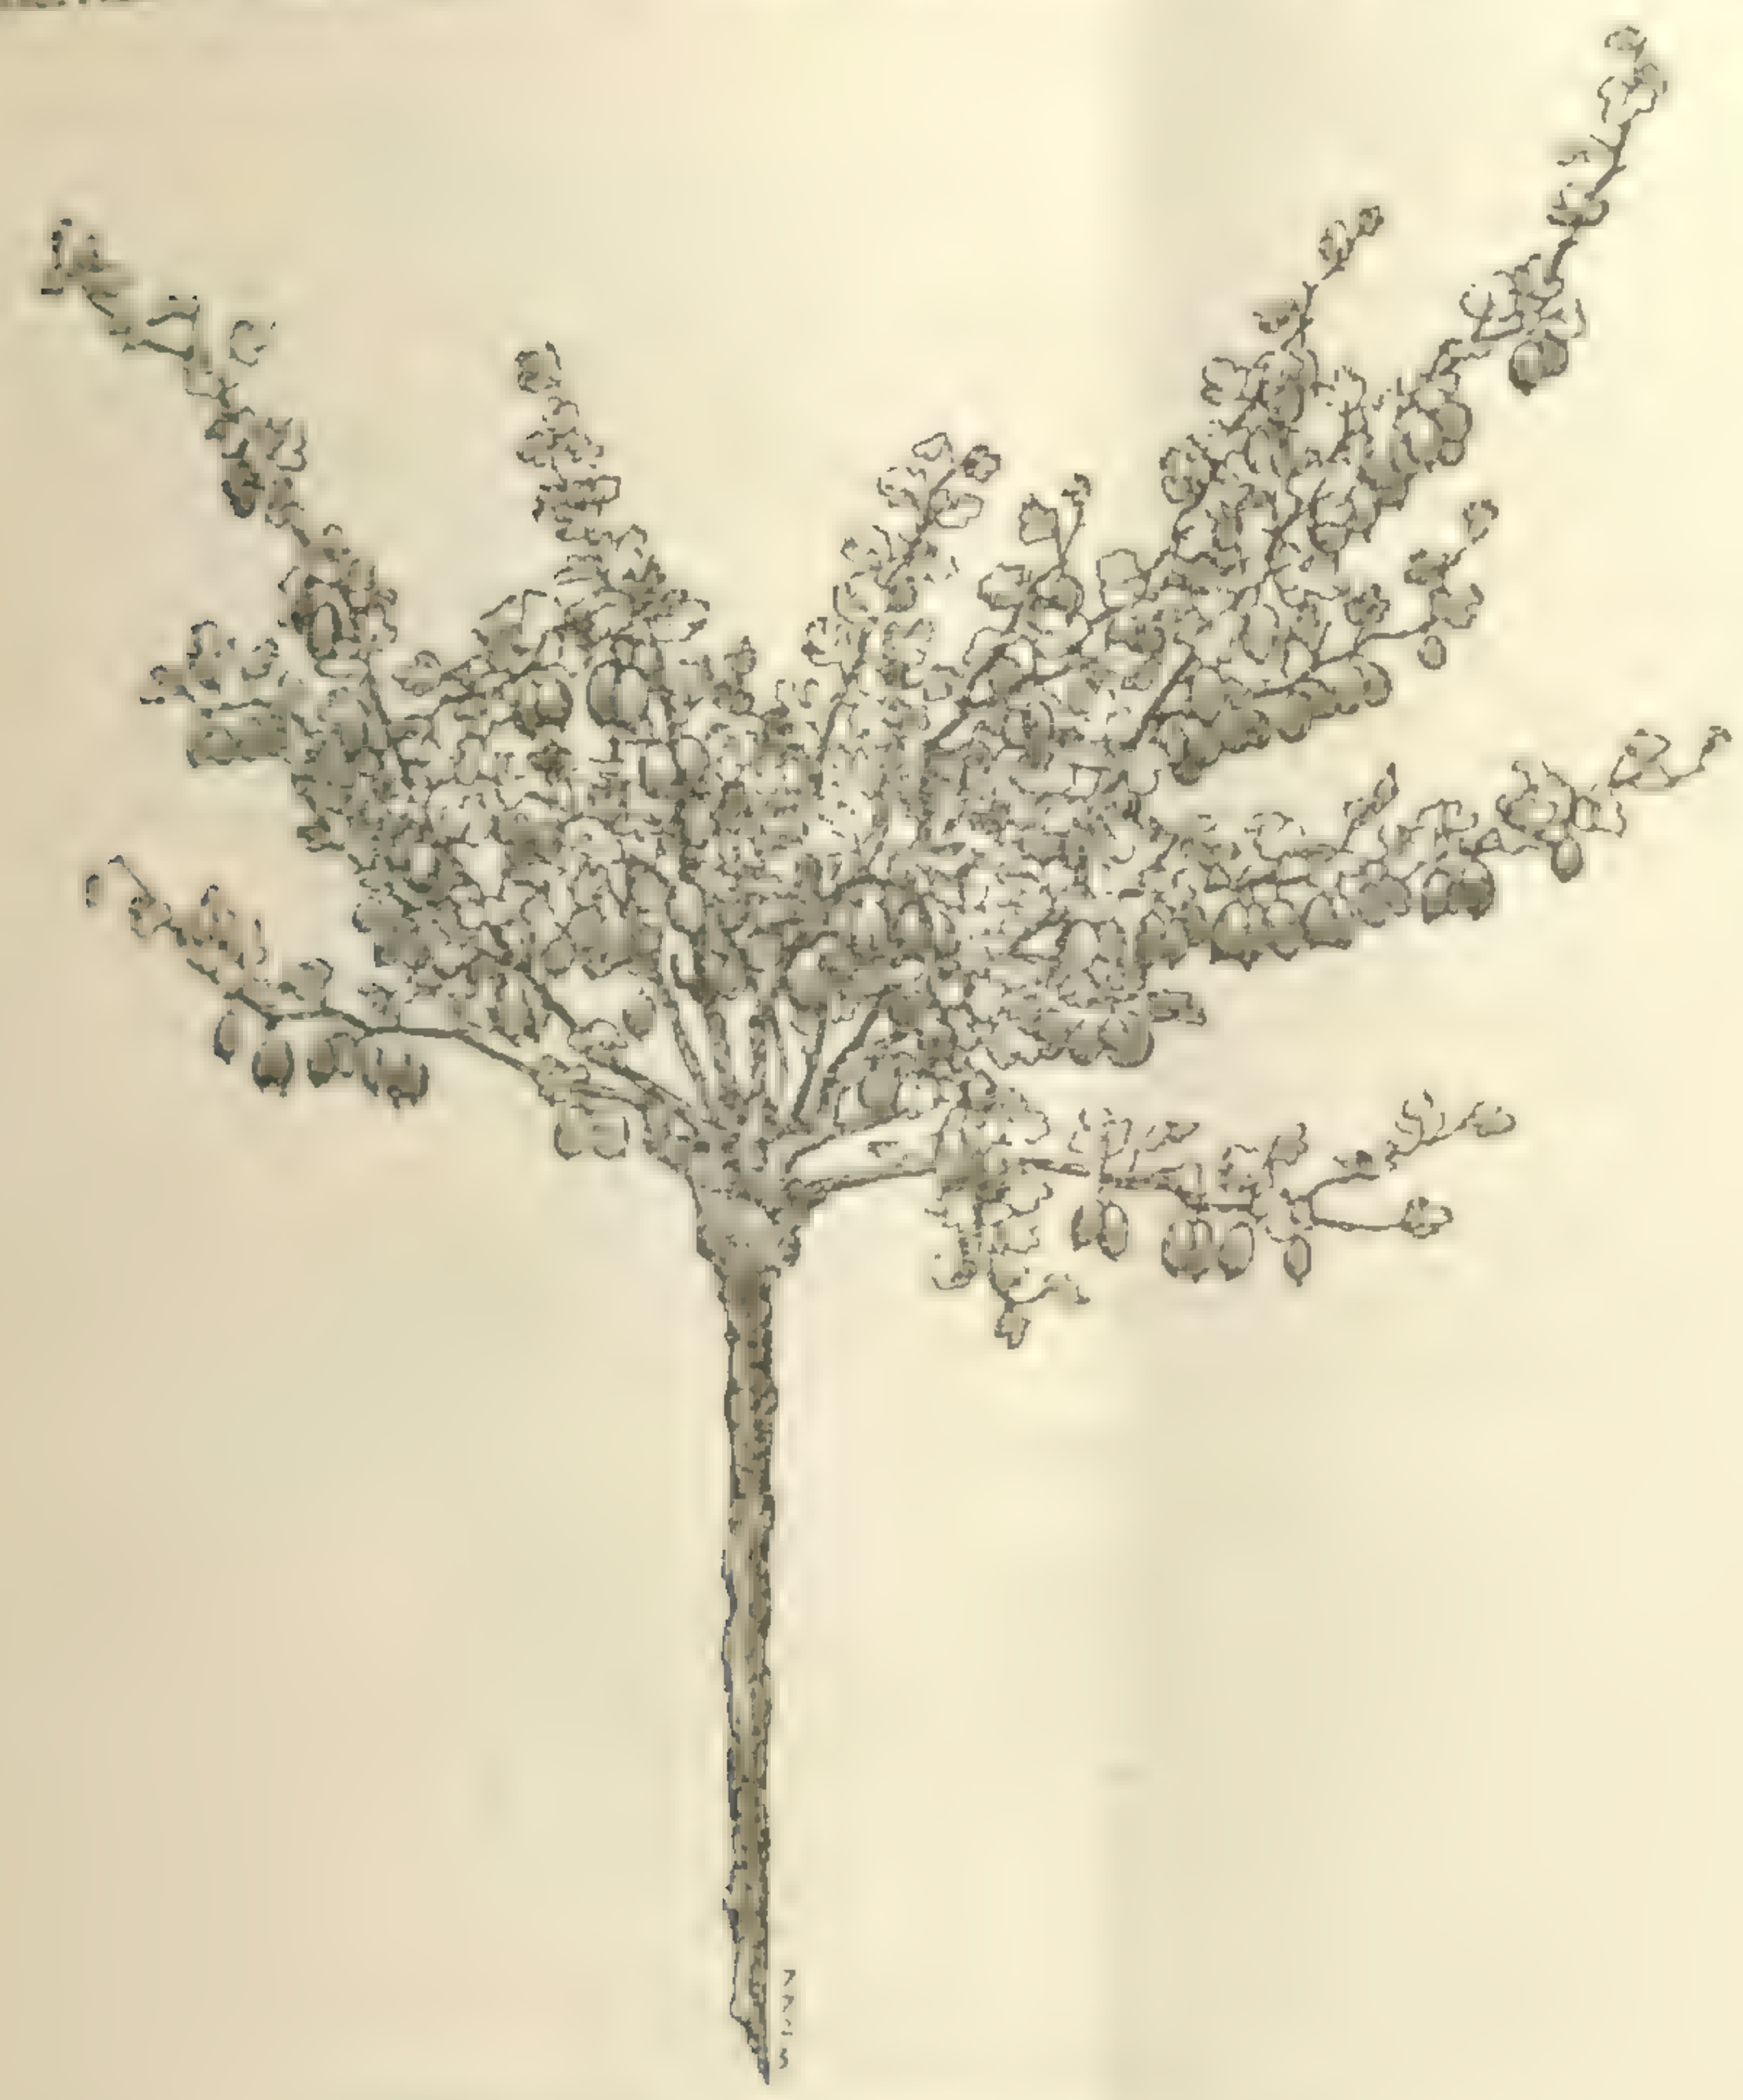
SPRING PLANTING OF CUCUMBERS.

THERE never could have been a better January for the raising [illegible] cucumber plants than was last month. Now, however, will come [illegible] time when firing is needed if the weather continues to be of the [illegible] character as during the last week. With me there has been no difficulty in raising plants, all being so wonderfully easy. Strong [illegible] planted will grow away without hesitation if they have the full [illegible] good bottom heat. Ours have entire new soil, and having previously thoroughly washed the house out the cucumbers have a fine start. At present our difficulty is in keeping down the small slugs imported with the turf and brought into life by the warmth. A little soot or wood ashes dusted round the hillock will render travelling rather difficult for them. Then, also, the whole house is baited with cabbage leaves, &c., and [illegible] we have to watch at night; for after all, as we know by experience, the young cucumber growth is more to their fancy than any bait.

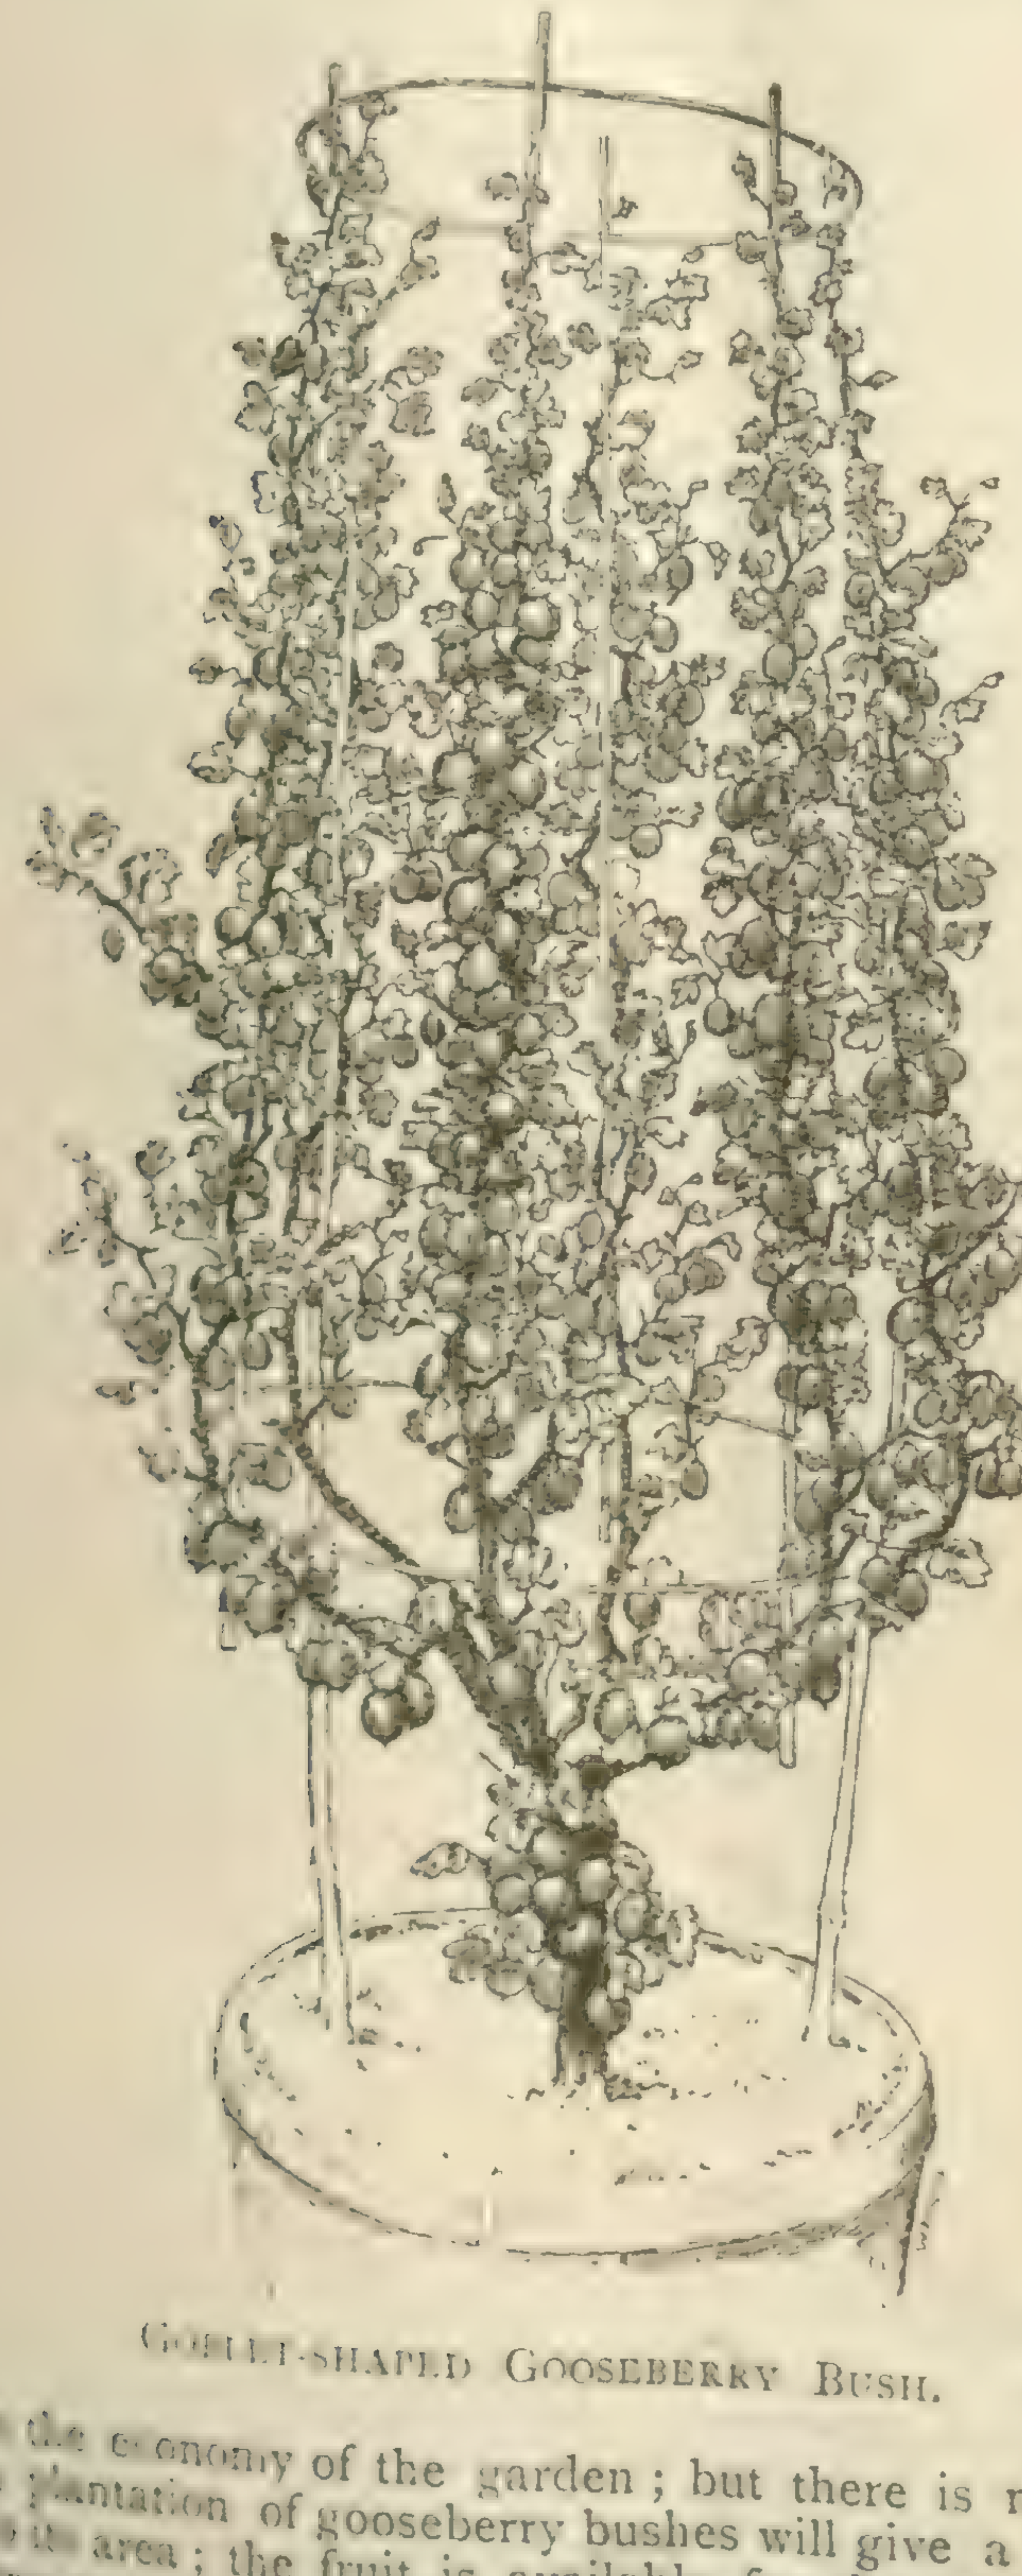
What little water the planted cucumbers will need must be given warm; indeed this is a necessity. That used for damping [illegible] border should also be tepid to prevent giving a chill to the [illegible] its best the cucumber plant is very tender, and especially when [illegible] in its new quarters. The growth, however, of such now [illegible] marvellous, and with days lengthening and sunshine more [illegible] indeed a pleasure to be among them, Our last house will be [illegible] March, and these I find from past experience are the heaviest croppers. Wind must be carefully guarded against, laying a rolled sack against the bottom of door to prevent draught. The glazing should also be [illegible] Though I do not syringe the cucumbers, yet when watering, the [illegible] well moistened; but when growth reaches the wire, except in very [illegible] cases, this is dispensed with. Plants should, under fair [illegible] no cleaning, for with all the aids to cultivation afforded as they [illegible] into fruit they should naturally be strong enough to keep them[illegible] clean. It is the weakly plants that are always attacked by insects.

Bottesford Vineries, Notts, STEPHEN CASTLE, F.R.H.

GOOSEBERRIES IN THE GARDEN.



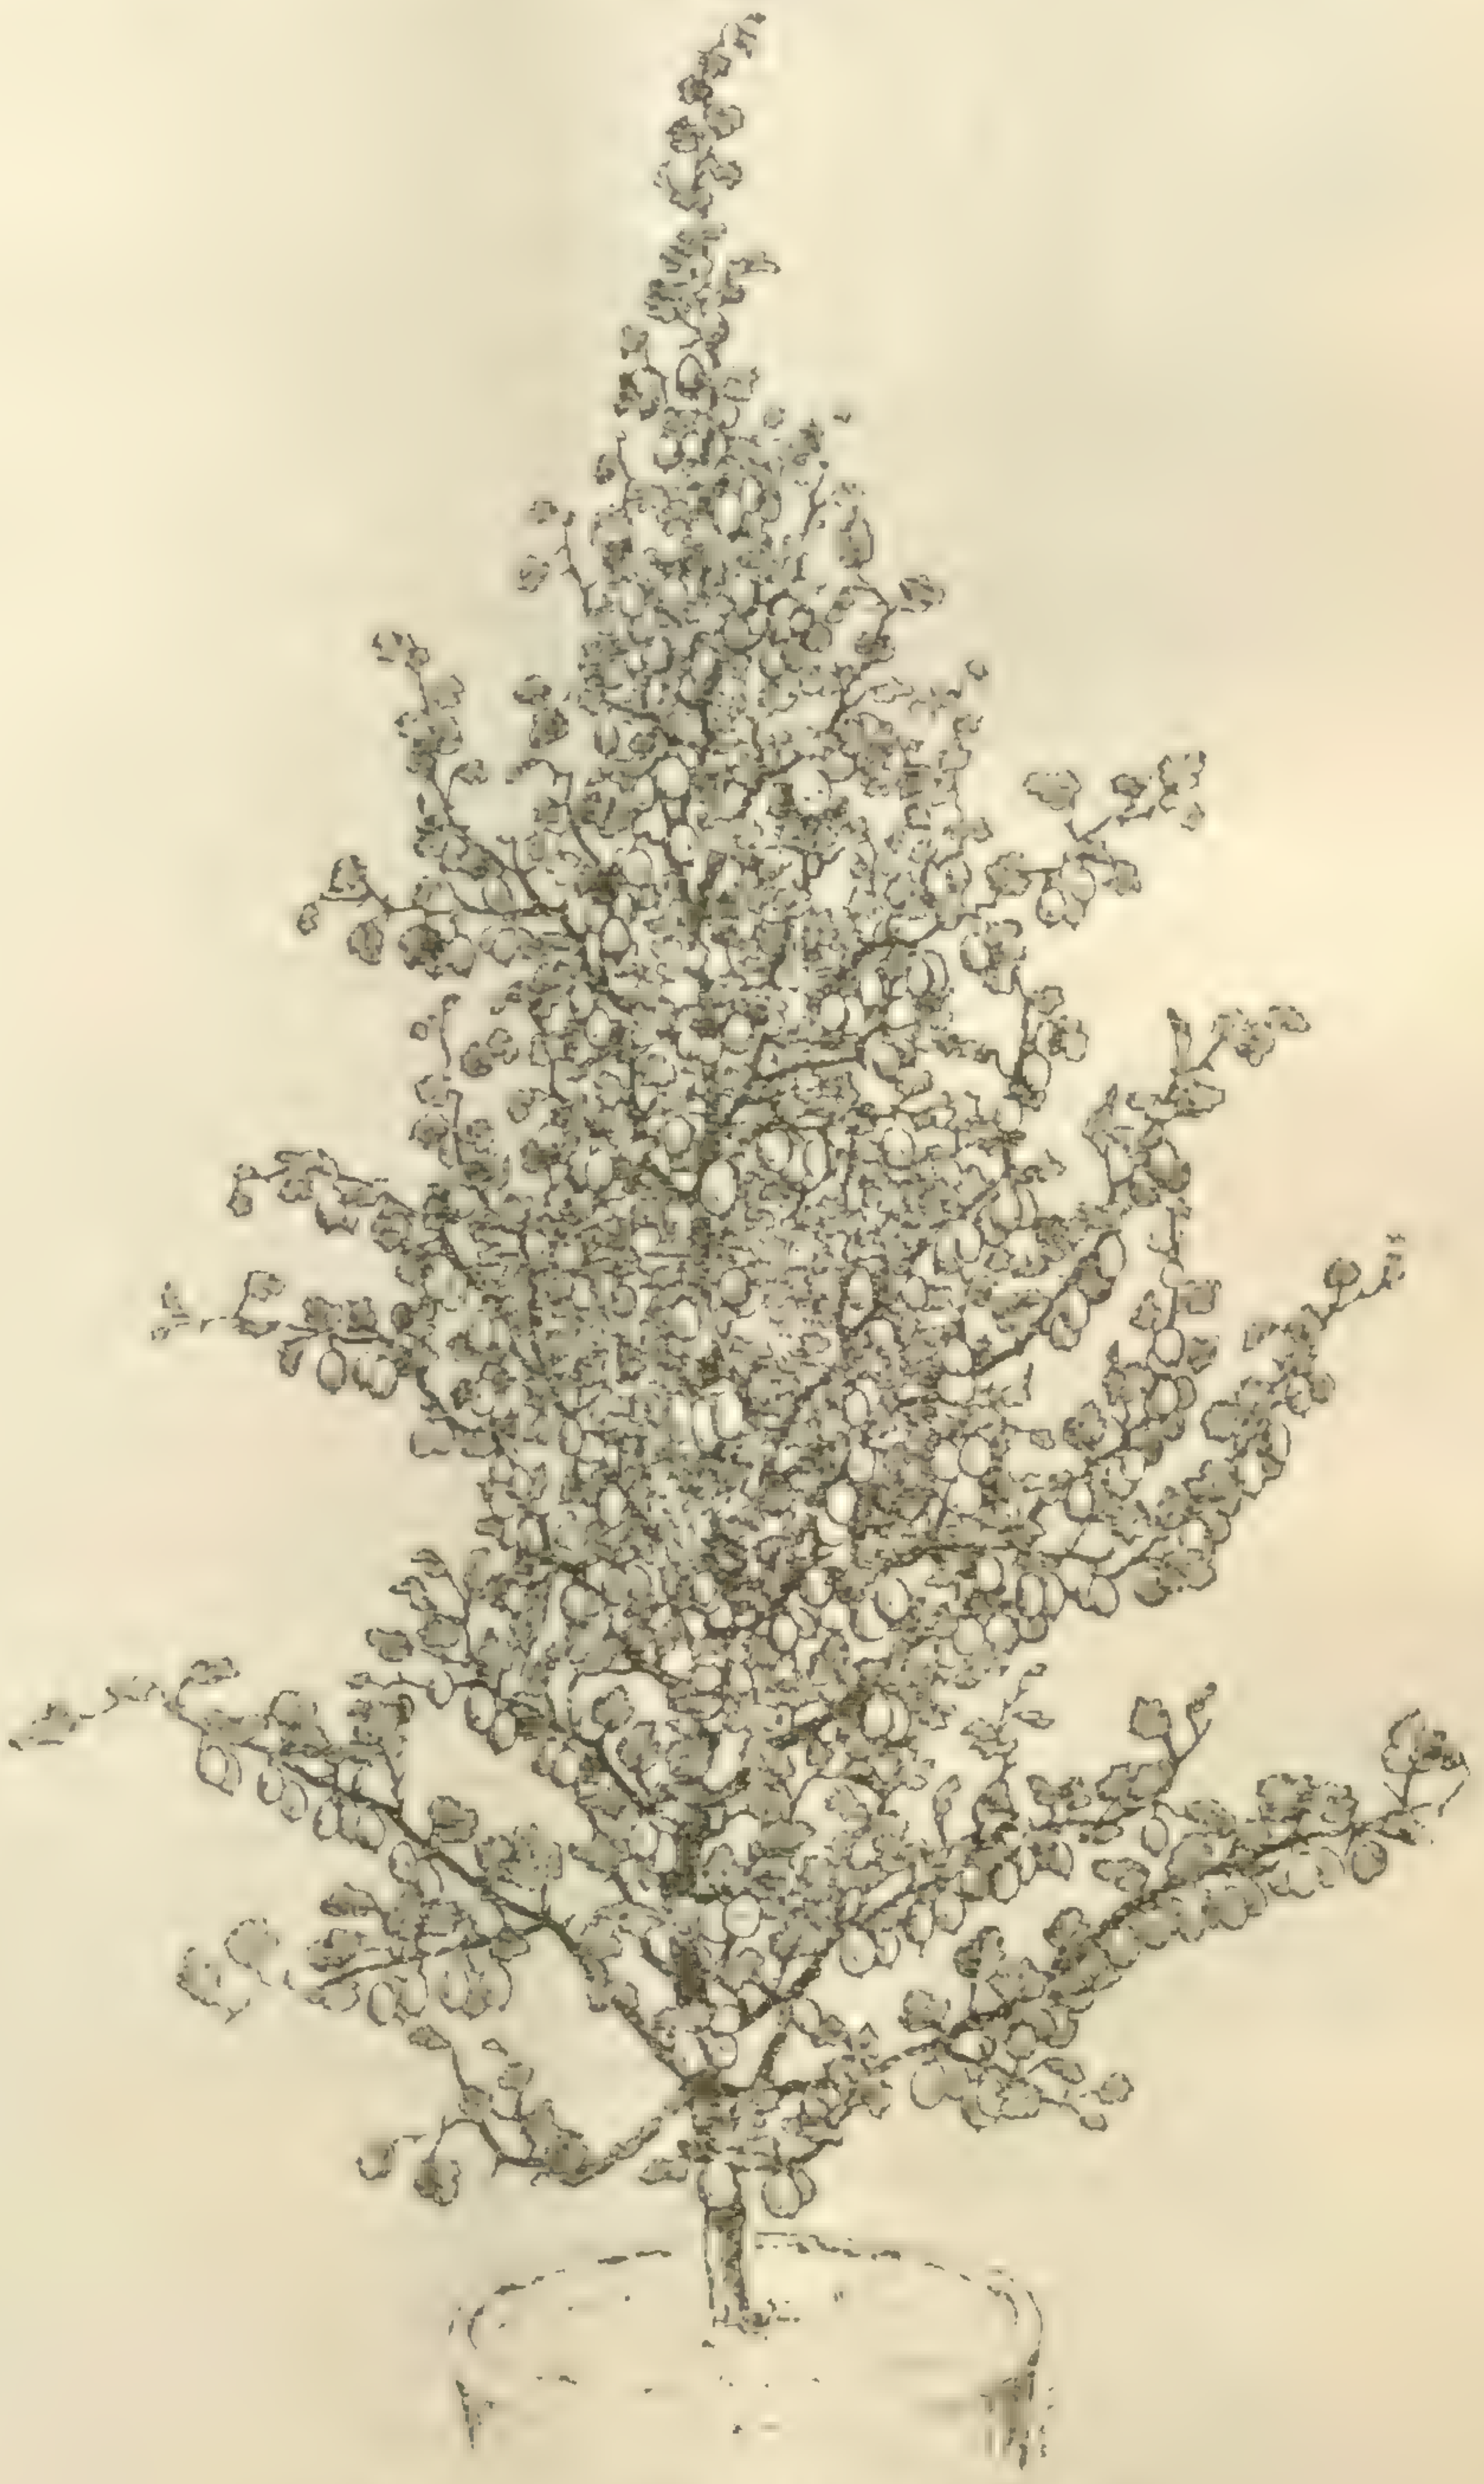
Standard Gooseberry Tree.



Goblet-shaped Gooseberry Bush.

That the cultivation of hardy fruits has undergone a remarkable degree of development during the past ten years is a matter of common knowledge; and it is also well known that in the production of both home and market supplies hard and soft fruits have equally shared in the advance. Gooseberries would appear to have received special attention, for they have been planted in enormous numbers; the increase being so great that nurserymen closely identified with fruit culture now sell a dozen bushes to every single bush they disposed of a few years since. This fact may perhaps perplex those who have not had opportunities for correctly estimating the value of bush fruits in general and the gooseberry in particular, in the economy of the garden; but there is no occasion for surprise. A plantation of gooseberry bushes will give a heavy yield in proportion to its area; the fruit is available for the table over a comparatively long period, as, unlike the produce of other bush fruits, it can be utilised with equally satisfactory results both in a green state and when it has attained its full maturity. The town dweller can have but an imperfect idea of the flavour of the fruit of the gooseberry in a ripe state. He has sufficient opportunities for formulating an opinion of green gooseberries as they usually reach the market in good condition; but the so-called ripe fruit has to be marketed before it has attained maturity, and in consequence of the practice which obtains of sending gooseberries to market in sieves, a considerable proportion of the fruit is smashed before it reaches the consumer. When it can remain on the trees until fully ripe, the fruit of the more highly flavoured varieties is at once delicious and refreshing. It is also remarkably wholesome, an attribute that is being more fully recognised, as indicated by the fact that in many gardens the plantations have been extended for the purpose of providing the children with liberal supplies when home for their summer holidays. Provisions are also being made in large numbers of gardens that have come under our notice for maintaining a supply well into August, and in the northern counties until September, as they are much appreciated at a time when the country house is usually full of guests.

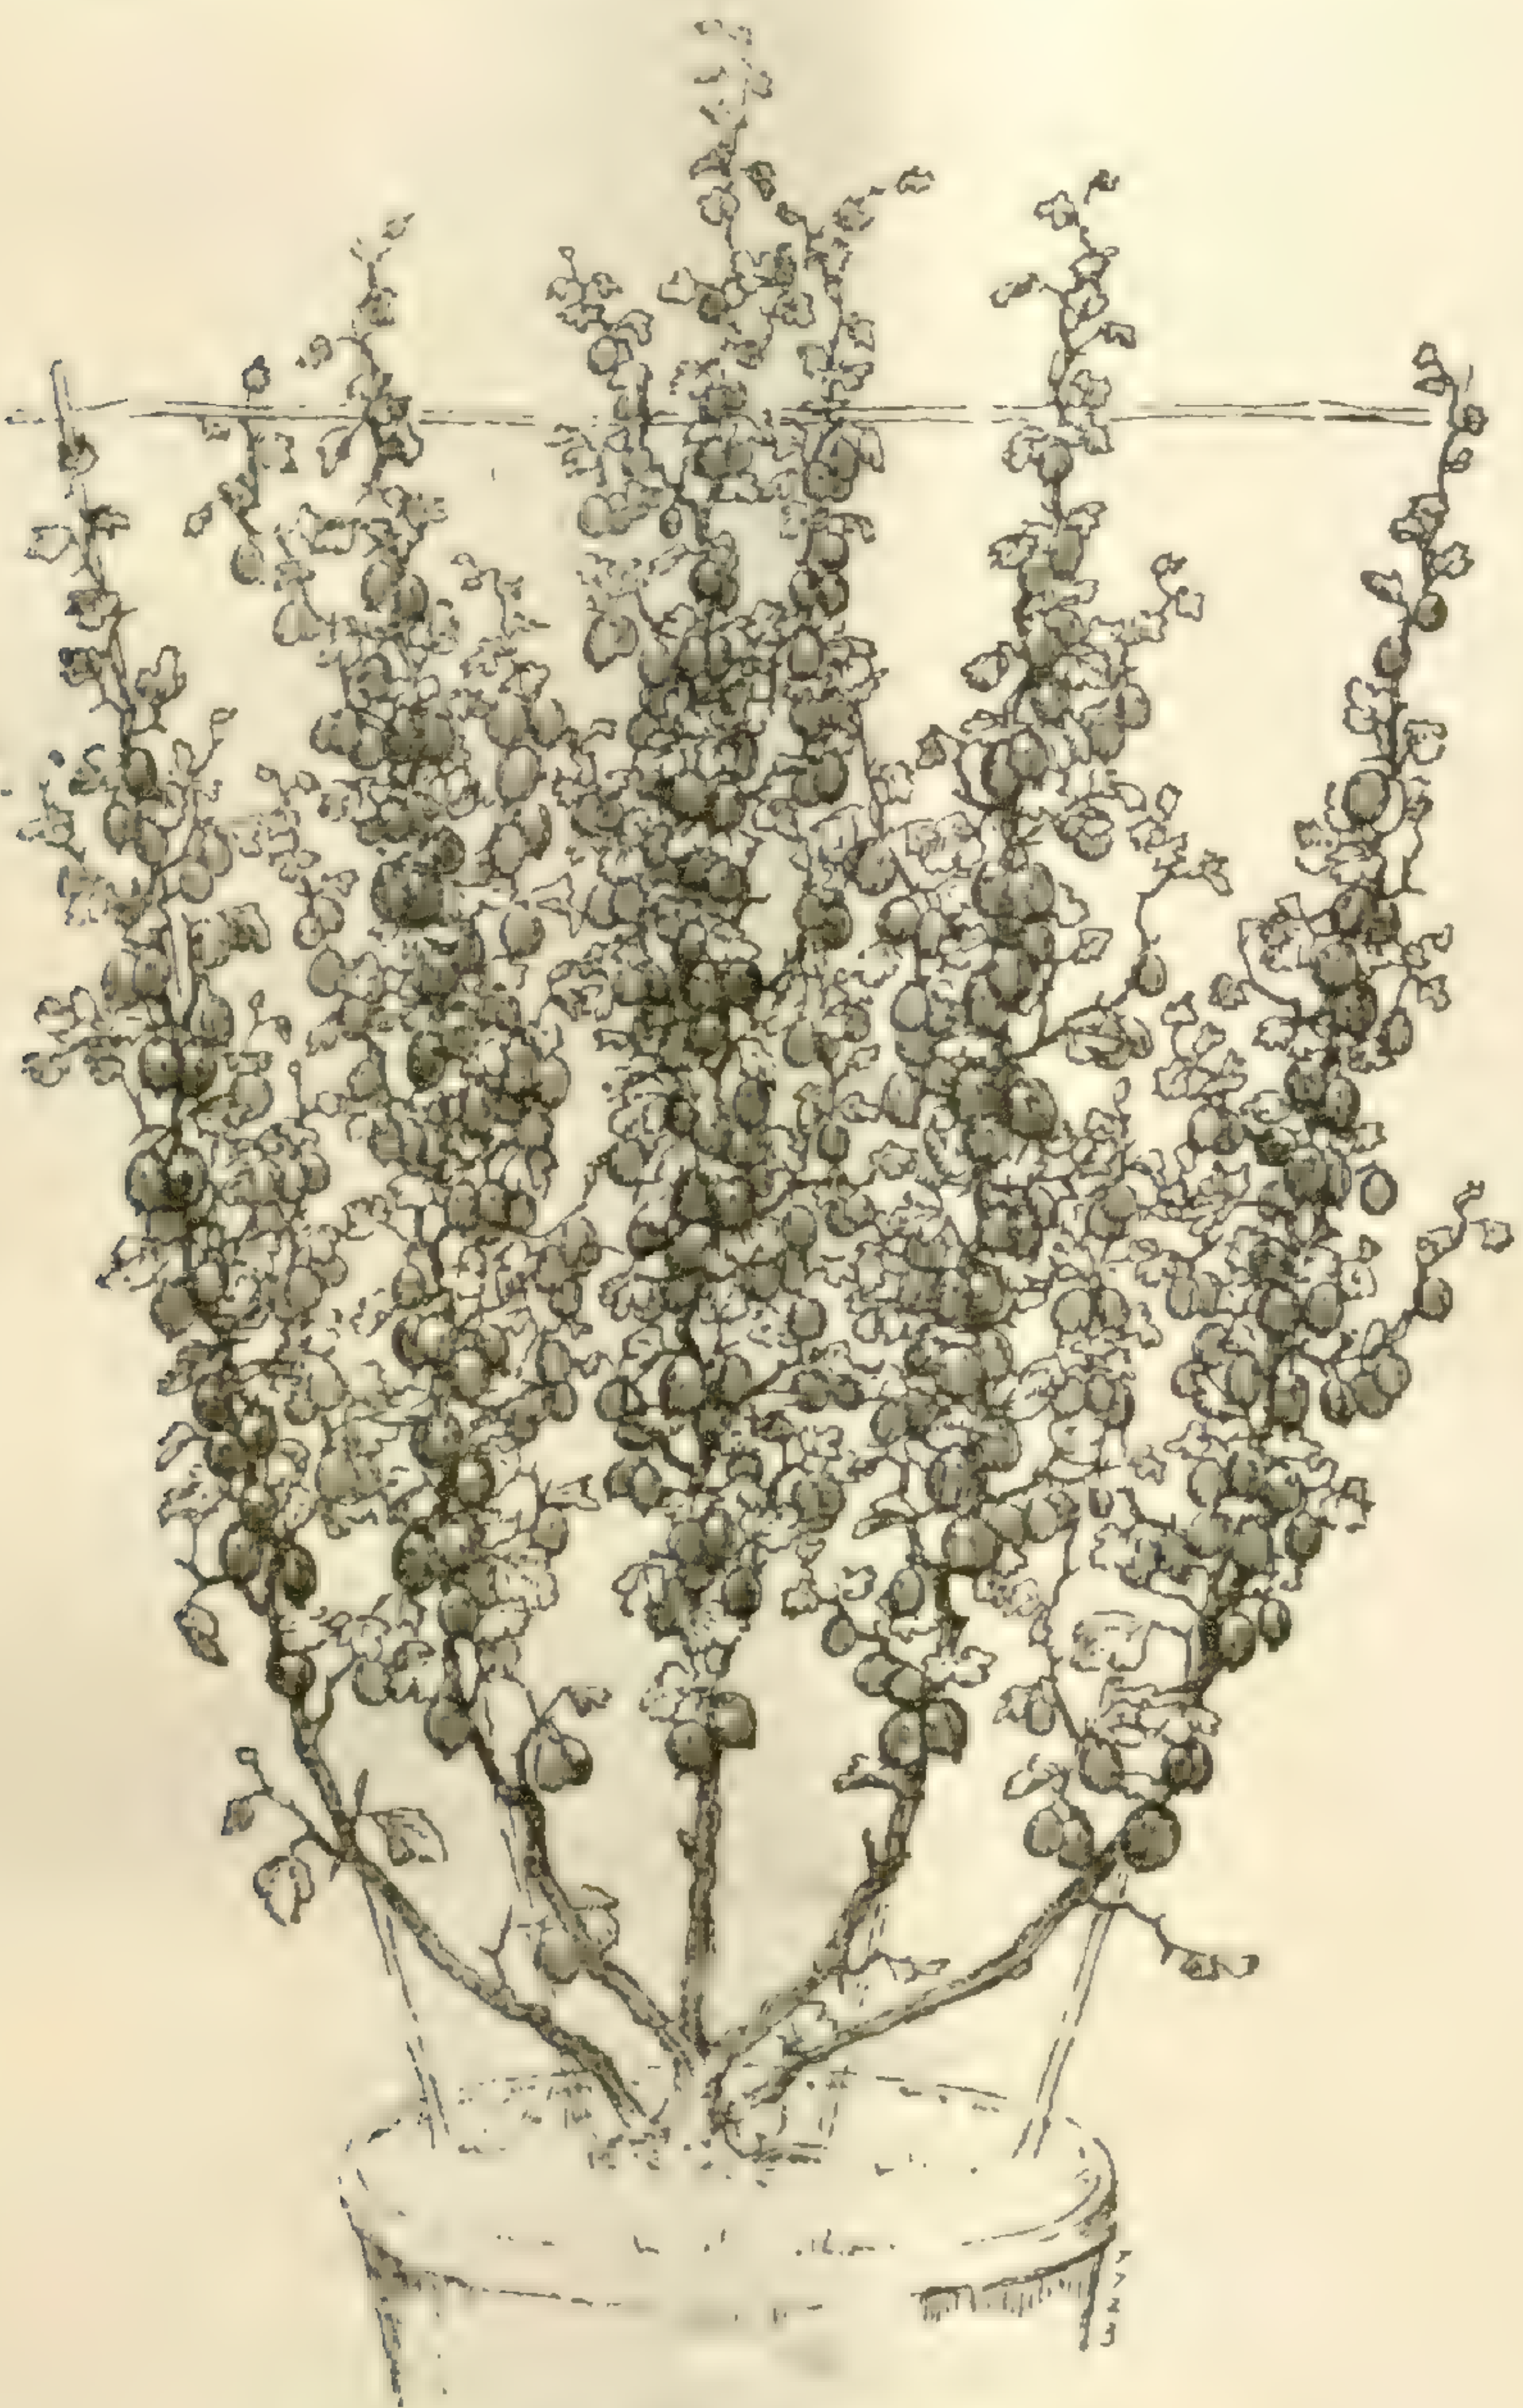
The gooseberry is perhaps less particular as to soil and climate than other of our hardy fruits, hence we see it thriving under the most diverse conditions throughout the United Kindgdom. As in the case of other bush fruits, an open sunny position is the most suitable for the plantations from which the principal supplies are drawn, as light and air are important factors in the development of the flavour of the berries. For late supplies a border on the north side of a wall ranging from eight to twelve feet high is the best place for the bushes, and when the wall space can be spared it is an excellent plan to cover the wall with cordon or fan-shaped trees, as these are usually very productive, and give an immense quantity of fruit in proportion to the wall space occupied. Then by filling the border with dwarf bushes the fruit required for use late in the season can, with a few light poles or strips of deal, and old fish nets, be protected from birds. At Castle Howard some such arrangement as this has been carried out by Mr. J. Riddell with the success that characterised the whole of his work in these important gardens, and abundant supplies were annually obtained until quite the end of the summer. Dessert gooseberries produced by bushes growing in the open should also be protected from the birds, as it is only when they are allowed to hang until they attain maturity that their characteristic flavour is fully developed. Old fish-nets carefully placed over the bushes will protect the fruit from the birds; but it is preferable to support the nets on a light framework of wood fixed five or six feet above the surface.



Pyramidal Gooseberry Tree.

The gooseberry is remarkably accommodating in the matter of soil; but like other fruits the best results are obtained when the roots have the advantage of a moderately deep loam in which to run. The private grower has but little choice in selecting soils for the several fruit crops, and has in consequence to make the best of those at his command. A deep loam is the best, because, while the bushes growing in it are able to make a vigorous growth and produce fruit of comparatively large size, the conditions are favourable to the ripening of the wood and the development of the flavour. On heavy soils the fruit frequently lacks richness, more especially if the drainage is not efficient, and where the soil is light and gravelly there is a great risk of the foliage becoming a prey to red spider and the fruit prematurely ripening. In the one case the soil may be improved by drainage and the addition of road drift or other gritty matter, and in the other by liberal dressings of decayed vegetable refuse and by mulching during the summer with half-rotted manure, grass mowings, or other light material that may be available. There is nothing better for applying to quarters occupied by gooseberries of which the staple is light than farmyard or stable manure, for while enriching the soil it materially assists in conserving the moisture.

The form of the tree must of necessity be determined by the position to be occupied, and the accompanying illustrations will be of considerable service in enabling the cultivator who has had but little experience except with the ordinary bush in making a selection adapted to his requirements.



MULTIPLE CORDON GOOSEBERRY.

These illustrations are reproductions of sketches made of some of the trees exhibited by Messrs. J. Veitch and Sons, at a meeting of the Royal Horticultural Society in the summer of 1897, and consequently show what has actually been accomplished. As the trees are represented as growing in pots it may be well to mention that they were lifted and put in them simply for the purpose of exhibition. The fan-shaped or multiple cordon is of special value for training to walls, fences, or trellises of wire and wood can be strongly recommended, for they are immensely productive. Cordons may have one, two, three, four, or five stems, but from three to four are preferable. The stems in all cases should be six inches apart, and the distance at which the trees are planted must be regulated by the number of stems. The pyramidal tree is well suited for the open quarters, as also is the goblet shaped, which has much to recommend it because of the full exposure to light and air the fruit obtains. In the majority of cases gooseberry bushes are allowed to become overcrowded, with the result that fruit is produced on the outside of the bush only, and the yield is less than it would be under more favourable conditions. It is a good rule to have the leading branches far enough apart to allow of the hand being passed between them without scratching, and in the course of the summer the young growths should be pinched or cut back to within a few leaves of the base, except shoots are required to take the place of old branches. Summer pinching involves but little time, and the superiority of the results will afford an ample return.

G.

On the Neutralising Action of Lime.—From three years' observations and experiments at Rhode Island Experimental Station, with various plants upon limed and unlimed soils, it was found that when the plants were treated alike in other respects there was an ill effect from the continuous use of sulphate of ammonia, which was not the case when an equivalent amount of nitrogen in the form of nitrate of soda was employed. Experience, however, showed that the ill-effect of sulphate of ammonia can be prevented altogether by the employment in connection with it of sufficient carbonate of potash, or by the use of wood ashes, or by air-slacked lime. Sulphate of lime (gypsum) failed to exert the same beneficial effect upon the growth of potatos as chalk, wood ashes, or air-slacked lime. These observations have been confirmed upon some light sandy soils naturally deficient in lime in this country, and lead to the conclusion that aside from a beneficial manurial or physical influence which air-slacked lime, wood ashes, or chalk, may have; they are probably useful in a high degree on account of a natural deficiency of mineral bases in the soil, and their ability to correct acidity (sourness) naturally existing or induced therein by artificial methods of cropping and manuring.—J. J. WILLIS, *Harpenden.*

CALIFORNIAN IRISES.

ALL Californian iris, so far as at present known, belong to the large group Apogon, or beardless iris, several of them being gems of the genus. Unfortunately, as is often the case with our treasures, these are difficult to manage, though there is one simple and most successful method of treatment which seldom fails. I have sometimes seen these iris advertised by American dealers at a time when planting them would mean certain failure, and the invariable remark from lovers of these charmingly beautiful plants has been, when recommending them, "If I knew how to grow the plant I would at once pay any price for it, but I have had it so many times, and it has never succeeded with me." Nearly twenty years ago we used to have importations of such kinds as Iris Hartwegi, Iris tenax, I. macrosiphon, and others, arriving, as a rule, in splendid condition in the autumn, but with the most careful treatment, rarely any of the plants ever made roots, or survived the spring. When sometimes the plants arrived during the spring the results were better, but still not more than 20 to 30 per cent. survived. The dealers had of course collected them during the autumn or summer, and they were kept laid in and then sent during the early part of the spring.

A few years later, through the kindness of a friend, I had a few plants, collected in the spring and sent, well packed, by mail; these consisted of Iris tenax, Iris Hartwegi, and a few plants of Iris Douglasi, all of which grew and flowered (I think in 1881) at the Hale Farm Nurseries. Accidentally Iris Hartwegi was lifted during the autumn, and though it kept alive over a year it never flourished again, and ultimately died. Iris Douglasi has slowly increased, and has flowered every year since. Of Iris tenax a whole bed, about ten feet long was raised, and there are still a few good pieces in existence, and these of a particular fine colour. Not having been able to secure another spring-collected lot of the Iris Hartwegi, and feeling sure that, after so many attempts, if tried again with autumn-collected plants there would be another failure, I have given up growing this species until I feel sure ,of success. These iris are not so particular about soil or climate, because as I have grown Iris tenax well in the open on soil consisting of heavy London clay, and again in sandy soil and ordinary loam, I feel sure that soil or climate is immaterial. Of greatest importance is, however, that they are not often moved, and then only during the spring when they begin to grow, always planting them again at once and rather shallow, giving an occasional watering during the first week. After that time they have made new roots and are safe. I speak, of course, only of the small growing kinds, which are at the same time the prettiest and most difficult; such species as Iris longipetala and I. missouriensis are easily managed.

IRIS DOUGLASIANA has very low and slender stems; creeping rootstock; leaves linear, evergreen and persistent, two to three feet long, dark green and often purple at the base. Flowers large, creamy white, lined and veined with crimson; falls rather long, with narrow standards; crests large. Flowering during the early part of the summer, this proves a very handsome species, being quite unique in habit and colour of flower. There is also a variety with lilac flowers and dark lilac veins, but whether this is the true I. Douglasiana I am unable to say.

IRIS MACROSIPHON has also low and slender stems and creeping rootstock; leaves light or glaucous green, linear, six to ten inches long, rather stiff and narrow; flowers small, rather graceful, lilac purple, tube somewhat filiform. The type flowers in May or June. Iris macrosiphon var. flava, is a form differing from the type in its shorter and broader leaves and bright yellow flowers. This form may, however, prove to be quite a distinct species; but as we had it under the name of I. macrosiphon var. flava, and also under I. m. flava var. nana, it is not for us to alter the name. It has the advantage of being much more easily cultivated.

IRIS TENAX has slender rhizomes; leaves tufted, linear, about four to six inches long and a quarter to half an inch broad, deep green, usually not evergreen; stems slender and short. Flowers comparatively large, bright lilac to rosy purple. This species is very free flowering and one of the most beautiful irises in cultivation. Flowers appear in May.

IRIS HARTWEGI has a slender creeping rootstock; leaves linear, six to nine inches long, deep green. Flowers bright or pale yellow, sometimes sulphur or white. Flowers are produced in May. This is the most difficuit of these Californian irises to manage.

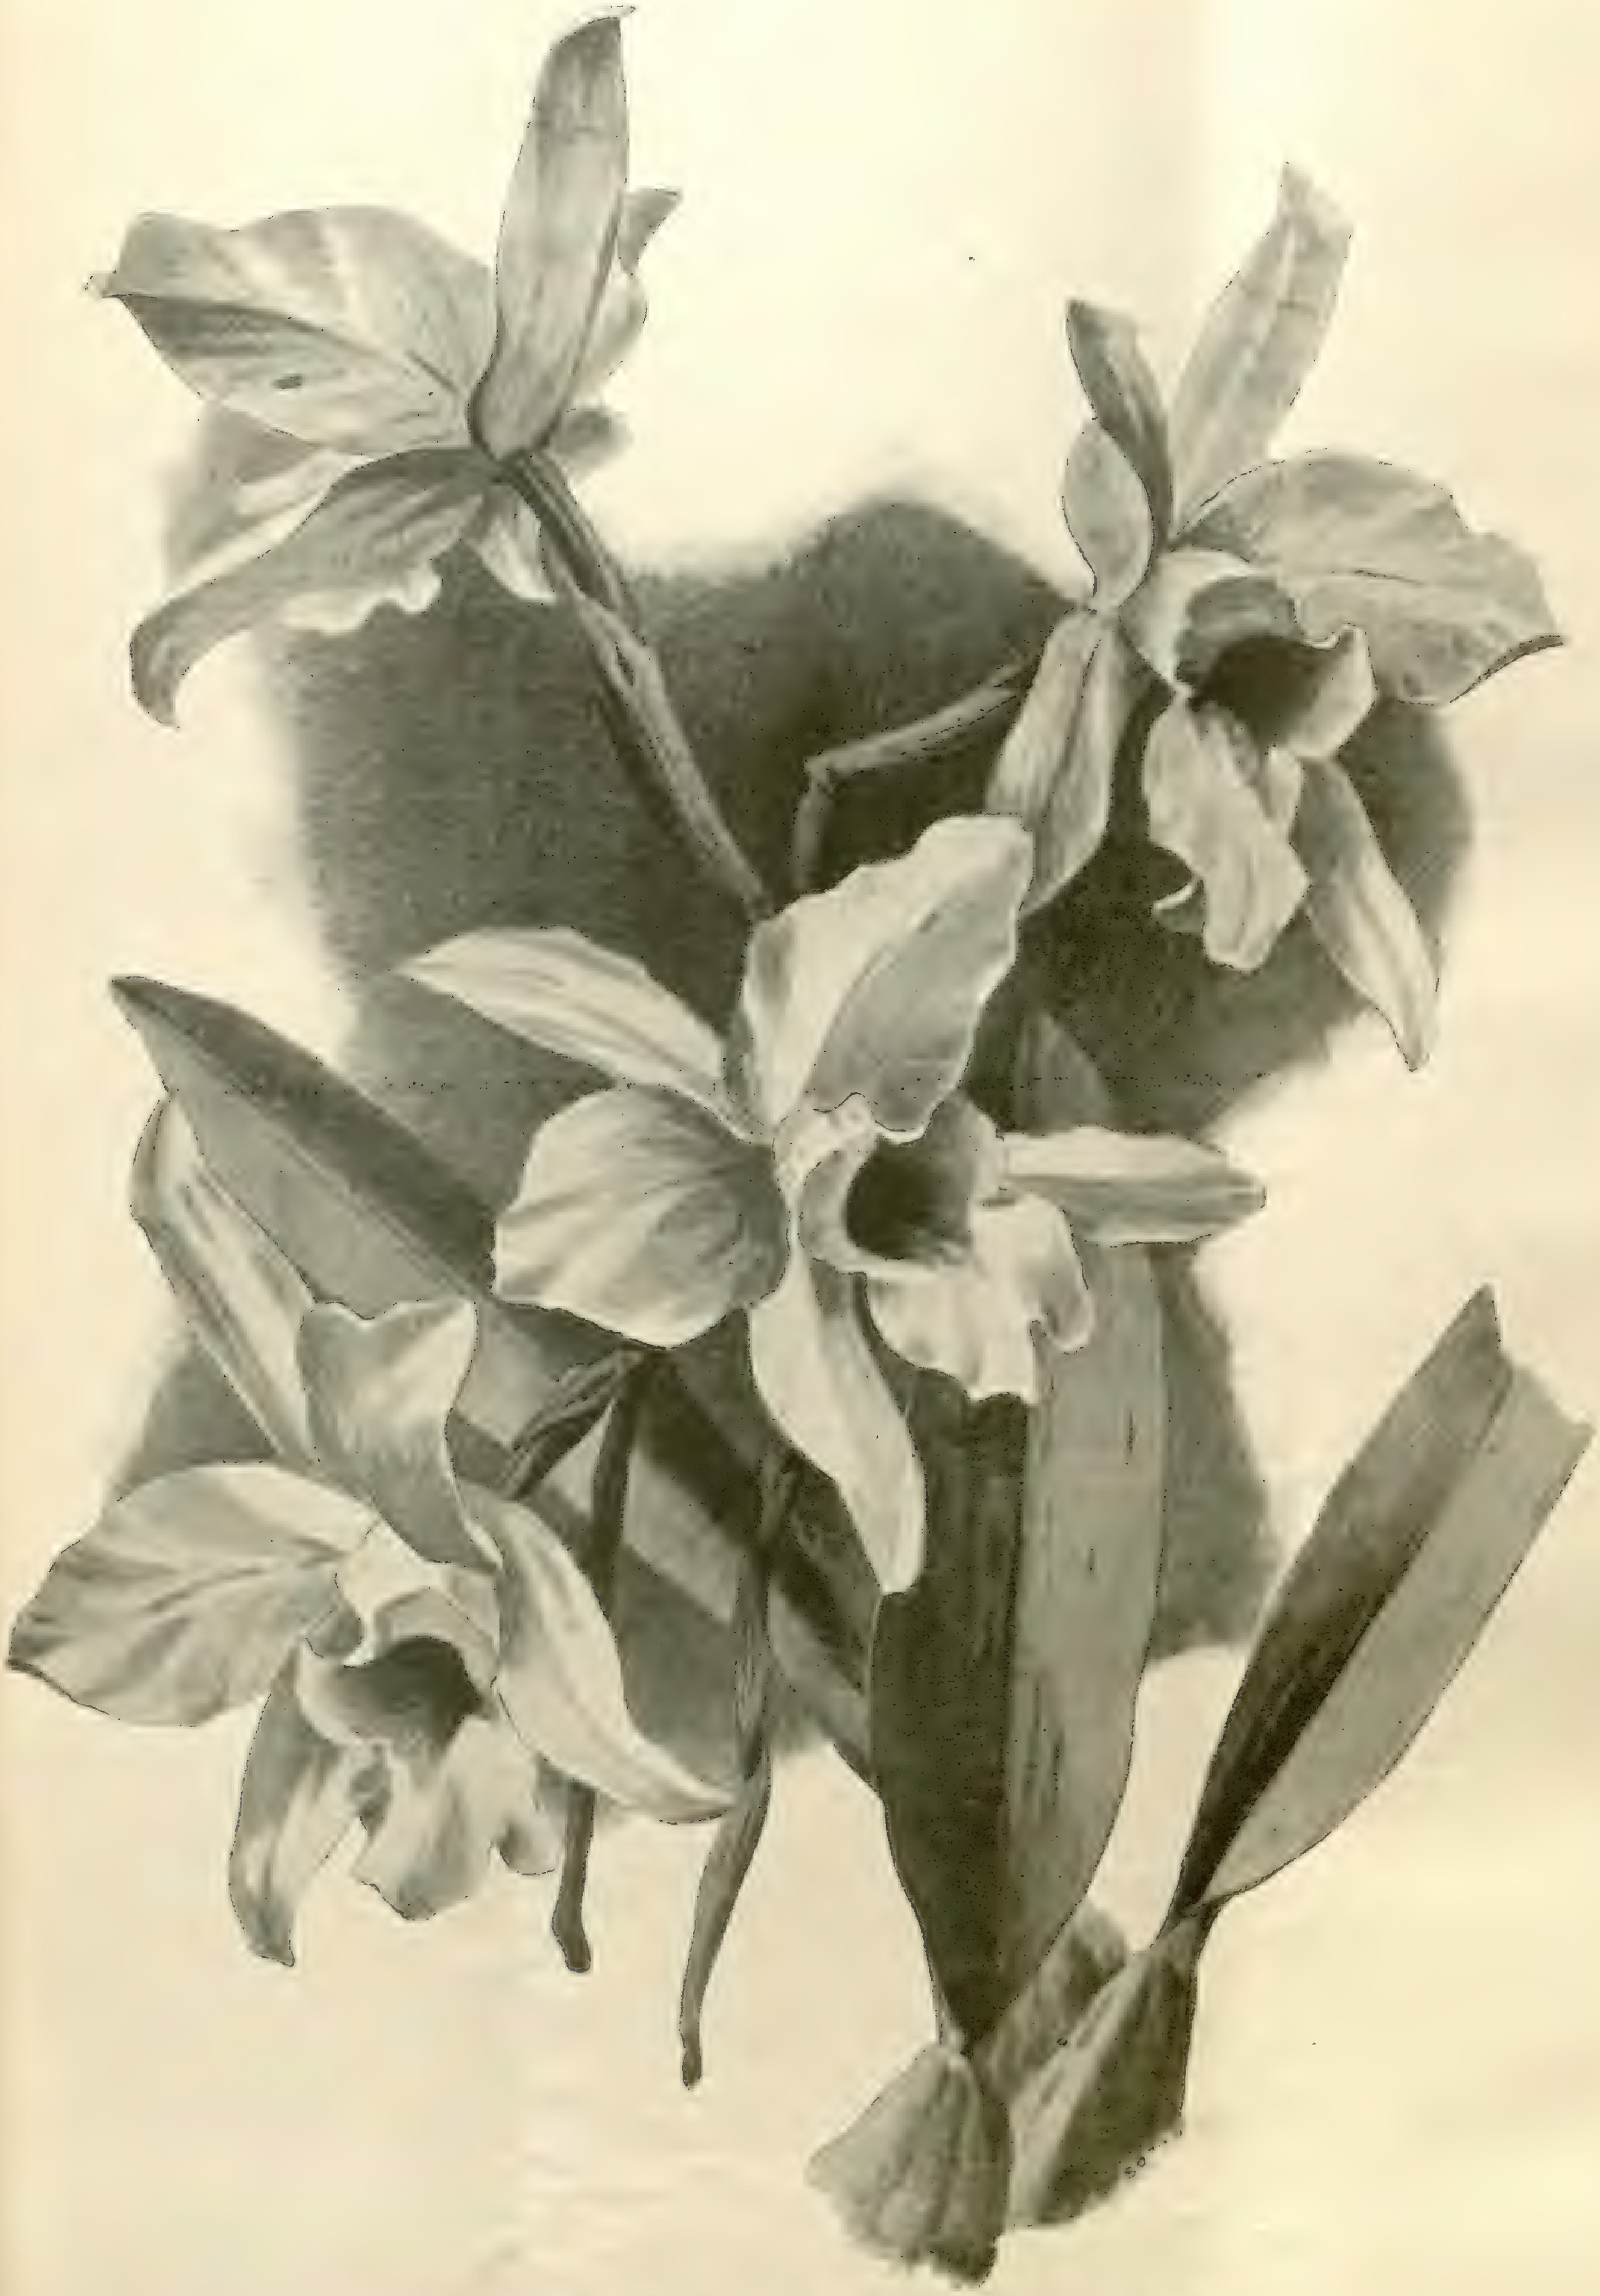
I. BRACTEATA produces tufted, linear, rigid leaves, nearly evergreen, one to one and a half feet long and half an inch broad. Flowers pale yellow and of a uniform colour. The plant is of very slow growth and flowers in May and June.

I. TENUIS has tufts of very thin and slender leaves about a foot long and one-third to half an inch broad. Flowers small, white or sulphur, veined yellow and pale lilac. At present this is a very rare species and seldom seen in cultivation. It flowers in April or May.

IRIS MISSOURIENSIS, besides being a very handsome species, is also one of the easiest to grow; its tufted, linear leaves, about one to one and a half feet long and half an inch broad, are glaucous green; stems one and a half to two feet in height, two or more flowered. Flowers large, pale blue, veined white. Flowers opening in March and April; one of the first of these iris to bloom. Being so very free this should be used for beds, especially when required permanently. It is very easily grown.

IRIS LONGIPETALA is of much coarser growth than the preceding; flowers larger but not so numerous, and produced later, in May. I. longipetala is also very variable, and crosses easily with allied forms, although intercrossing does not seem to improve them much. What is known in gardens as I. Tolmiana seems to be a cross between I. missouriensis and I. longipetala, and has paler flowers and broader and longer leaves than I. missouriensis. Iris longipetala compacta is a cross between I. longipetala and probably I. spuria; of compact growth, with broad, uniform leaves, and pale blue, white-veined flowers that are larger than in the two preceding. I. californica or I. longipetala minor is allied to Iris missouriensis, but has not free habit, and flowers later.

G. REUTHE.



LÆLIA ANCEPS WADDONIENSIS. (Flowers white and yellow.) *See age* 112.

WORK FOR THE WEEK.

COOL ORCHIDS.

THE present time will be found the most suitable for dividing and potting overgrown specimens of masdevallias such as M. ignea, M. Harryana, M. Veitchi, M. Lindeni, M. polysticta, and M. tovarensis. The pots or pans used for masdevallias should be three parts filled with clean potsherds, covering this with a thin layer of sphagnum. The compost should consist of peat of good quality with the dust shaken out and living sphagnum, using this in equal parts with a little coarse sand added. A little fibrous loam may be added with advantage for the stronger growing kinds such as M. Harryana, M. Veitchi, and M. Lindeni, as these require something more to root in than most others. Plants that are in good health should be turned out of the old pots, removing a little of the loose material, but taking great care not to injure the living roots, placing them in pots a size larger, pressing the compost moderately firm. In the case of sickly plants or any that have become exhausted in their old receptacles, should have all the old material removed and the decayed roots cut away; small pots should only be used. In potting such plants should not be raised much above the rim, or it will be found very difficult to make them secure, and if left in an unstable condition they cannot become re-established; small neat stakes should be used to keep the plants firm. A few fresh heads of sphagnum moss pricked in over the surface of the compost will soon grow, and greatly improve the appearance. Specimens that only require top-dressing should have the old material picked out and replaced with new. Great care should be taken in watering after repotting, until the new roots have a good hold of the compost; the surface may be kept most with the aid of a fine rose-can to induce the sphagnum to grow. Should cold weather prevail it will be prudent to remove M. tovarensis to the coolest part of the intermediary house.

Masdevallias of the Chimæra section should also be attended; these are best grown in teak-wood baskets, and suspended close up to the roof. The potting material should consist of peat and sphagnum moss in equal parts with some finely broken crocks and charcoal intermixed, as no crocks should be used for drainage owing to the spikes growing downwards through the bottom and sides of the baskets; after rebasketing place in the most shady part of the house, and on bright days spray over them, by means of a syringe, using tepid soft water to keep the compost sufficiently moist, and prevent the attack of red spider. These masdevallias are best grown in the coolest part of the intermediate house during the winter months. Lælia harpophylla, a beautiful species with its bright vermilion-coloured flowers, will be making a nice show just now, and cannot fail to give satisfaction to those who grow it successfully; after they have passed out of flower the young growths start from the base of the stem-like bulbs, and only a moderate supply of water must be given until root action becomes brisk, and the young growths are well advanced, then a full supply of water may be allowed. This species are sometimes grown in the intermediate house, but it may be grown with equally good results at the warmest end of the odontoglossum house.

With increased sun heat the day temperature may rise a few degrees, but afford the same care in ventilating, damping, and watering. Cool houses that are in an open position should have the roof shading fixed ready for use, as the plants having passed through the dull wintry months are unable to bear the sudden bursts of sunshine that sometimes now occur in the middle of the day.—E. SHILL, *New Hall Hey Gardens.*

STOVE PLANTS.

THE middle to the end of February is the most suitable time for sowing seeds of gloxinia, Saintpaulia ionantha, Isolepis gracilis, Cyperus alternifolius, asparagus in variety, &c. There is very little gained by sowing them in January—the short, dull days and the extra reliance that has to be placed upon artificial heat is against the free germination of the seeds. Sowing at the time stated above will generally give the best results, as the lengthening days and the increased light, will all be in favour of the young seedlings growing away without any check. Pans and six-inch pots are the most suitable for seed vessels, and should be filled at least one-third of their depth with crocks, the larger at the bottom, and finer on the surface, over these a covering of moss, and then the compost in which the seeds are to be sown. This should consist of equal parts loam, leaf soil, and cocoanut-fibre refuse, with a free admixture of sand. Pass through a quarter-inch sieve, and place an inch and a half to two inches of this into each pot or pan over the moss; then sift the remainder through a finer sieve, and place half an inch of this finer soil in each pot or pan, press level, and give each a watering with warm water, and stand in the house where the seeds are to remain while germinating. When the water has drained away, the seeds may be sown evenly over the surface, and in the case of very small seeds, no covering of soil is necessary—merely press the seeds into the soil: larger seeds may have a covering of soil equal to their own diameter. When sown and duly labelled, cover each with a sheet of glass, and then the glass with moss or paper. When it is necessary to afford water to pans or pots containing very small seeds, do not water overhead, but stand the pot containing the seeds in a vessel of water, and the upper layer of soil will become moistened as a result of capillary attraction.

Propagation of all classes of stove plants may now be proceeded with apace. Where a large amount of decorating has to be done, especially table decorations, the propagating case will be in constant use. We propagate large quantities of crotons, dracænas, acalyphas, pandanus, fittonia, pilea, and other things for this purpose; the cuttings are placed singly into thumb pots, and when rooted they are hardened off and kept in the thumb pots for use on the dinner table. It is surprising how long they can be kept in a presentable condition in these small pots by judicious feeding. When taking suckers of Pandanus Veitchi, avoid those strong ones which throw out from the axils of the leaves, taking in preference those very small ones which are to be found at the base of the plants, as these will make for the best plants, and if grown in poor soil will show a great deal of the white variegation, the leaves also arching more gracefully. Keep the suckers somewhat dry and free from drip until roots are formed. Crotons may be rooted at this season without the loss of a leaf. Make the soil firm around the base of the cutting, tie the leaves up carefully to a thin stake (not too tightly); when plunged in the propagating case allow each one to stand clear of its neighbours, syringe them overhead four or five times daily, and keep the soil moist at all times, but not too wet. Aralias are useful subjects for many purposes—in fact, they are so graceful that one could hardly place them wrong. With the exception of A. reticulata and A. Guilfoylei they are not readily raised from cuttings, and grafting is resorted to for the purpose of increasing the stock of such varieties as A. Veitchi, A. elegantissima, and A. leptophylla, using as stocks the two first-mentioned species; after grafting place in the propagating case. Old plants of acalyphas that have lost their lower leaves may now be cut freely in, the points may be inserted to increase the stock, and the old stools kept dry until they break freely into growth.

Bougainvilleas may now be pruned. These are glorious climbers, but B. glabra and its forms are not seen to the best advantage in the stove, an intermediate house suits them better; in such a house they bloom more freely, and the flowers are of a much better colour than is generally the case in the strong heat and moisture-laden atmosphere of the stove. In pruning spur closely in, and afterwards afford the stems a washing, and give a rich top-dressing. Plants of Clerodendron Thompsoni should now receive attention; thoroughly soak the old ball with tepid water, and any that require repotting should be attended to, using as a compost good fibrous loam, leafmould, a little well-decayed manure and silver sand; after repotting give water cautiously until the roots are working freely in the new soil. Those plants which are to be retained in the same pots should have the drainage examined and receive a rich top-dressing. Syringe the plants overhead two or three times a day to induce them to break freely. More tubers of gloxinia, achimenes, and caladium should be started.—J. TUNNINGTON, [illegible] *Castle Gardens.*

KITCHEN GARDEN.

THERE is much work that can be done in this department at the present time that will greatly facilitate matters later on; therefore, anything that can be taken in hand now should on no account be neglected. Pea stakes should be procured and sharpened, and put together in sizes for peas of different heights; bean sticks may be treated in the same way. Any box edging that needs replanting should also be attended to while the weather is suitable, and after all wheeling is done the garden paths should receive attention. If any require regravelling this should be done while the ground is moist, as the gravel will bind best when in such condition. The days are now lengthening, so that work in every department will be more pressing, and as that in this is often neglected it is well to bear in mind that those who would avoid any complaints must be well prepared with abundant supplies. The cabbage plot should receive attention by having the spaces between the rows sprinkled with nitrate of soda. If any weeds are showing themselves the ground should be pointed over when sufficiently dry on the surface to prevent its being picked up by the boots. Shallots may now be planted, and those who desire them for exhibition purposes should select sets that are not likely to split up too much, and these should be planted a sufficient depth to prevent the roots from lifting the bulbs out of the soil. The ground in which these are grown cannot well be too rich if large well-shaped bulbs are wanted. When the soil is in a workable condition a small sowing of carrots may be made on a warm border. It is always far better to defer digging such ground till the time of sowing, as it works much more freely than when dug in the autumn, the particles of soil being closer together do not retain so much moisture. If dug and sown as the work proceeds far better results will be obtained than from ground that has become sodden or made pasty by frost. A small sowing, too, of lettuce and radishes may also be put in. Care must be taken to protect the latter from birds, which are very troublesome at this time of the year.

Forced vegetables will now be in great demand, therefore ample provision must be made for their growth. Roots of both tarragon and mint must be introduced as the older lots become exhausted. It is a good plan to have a stock of cuttings of both these put in boxes in August; they will root freely at that time of the year, and the boxes may be introduced into heat as required. Small sowings of such things as chervil, celery, basil and savory should also be made in pans or boxes, as the young foliage of these is much esteemed by most cooks for flavouring. The young leaves of sorrel are often in request, so that a few boxes of it should be placed on a slight hotbed to induce a free growth. Salads of all kinds must not be neglected, for where there is a constant demand for these small but frequent sowings should be made of mustard and cress, while endive, chicory, dandelion, &c., should be introduced into heat in small quantities to keep up the supply. A small sowing of tomato seed should also be made, but it is well not to put in the main lot until the weather is a little warmer, for the more freely the plants grow with an abundance of light and air, the shorter-jointed and more robust will they be.—H. C. PRINSEP, *Buxted Park Gardens.*

FRUITS UNDER GLASS.

THE varieties of grapes chosen for early forcing are, or should be, always free setting, and should be thinned as soon as the berries become large enough to be easily singled out, as there is no need to wait for fear of some berries being stoneless. Early grapes should not be thinned so freely as mid-season and late varieties, as they rarely swell so much, and as they are generally cleared off soon after they ripen there is no fear of damping. Laterals should be stopped at one or two joints beyond the bunch, allowing the latter number of joints where there is plenty of room between the rods, it being better to allow one or two extra main leaves than to force a very early crop of sub-laterals. Keep the house fairly moist in bright weather but avoid too much moisture, the presence of which is soon made known by the appearance of air-roots on the stems and warty excrescences on the under sides of the leaves, both of which are bad signs, which, if encouraged, will most certainly lead to shanking. I do not pretend to say that they are the cause of shanking, but I have rarely, if ever, met with shanked grapes on vines that have not carried also a crop of aerial roots. Vines in flower should have the atmosphere kept rather dry until they have passed this stage, and the bunches should be tapped or have the hand drawn carefully down them on bright days at mid-day. The present is a good time to start a mid-season house, it being better to give the vines plenty of time than to hurry them later. Muscat and other late houses should be made ready for starting; the borders should have the necessary attention in top-dressing, and those which are at all dry should receive a thorough soaking of tepid water. I find that the last week in February or the first week in March is the best time for starting late vines, for the grapes are then ripened under the influence of full sunshine, instead of having to be helped by artificial heat in the autumn. The ventilation of vineries at work must be on careful lines, avoiding anything in the shape of front air or draughts from any cause, as these are certain causes of mildew; the necessary air should be given at the apex, and shut off again soon after mid-day.

Early melons must be potted on or planted out before they become pot-bound. Whichever method is chosen, the soil should be thoroughly warmed first, and should consist of heavy loam with a good sprinkling of broken mortar rubble. Where the only available loam is of a light nature, one of the best correctives with which I am acquainted is brick earth, and this may be used in a proportion of from one-third to one-half the bulk. An excellent system under which good crops of melons can be grown, and which counteracts in a great measure the tendency the plants have to canker at the collar, is a combination of the pot and planting-out systems. When the young plants have filled their pots, which may be anything from four inches to six inches in diameter, with roots, the bottoms of the pots should be gently broken away until a hole large enough to allow of the escape of new roots has been made, then the pots should be plunged into hillocks of soil made up in the usual way, and into which the roots run freely; the pot rims should stand an inch or two out of the soil, then the collars may be kept dry or nearly so. A bottom heat of 75 degrees must be kept up, and a minimum temperature of [illegible] degrees is suitable for top growth, keeping the plants always as near as possible to the roof glass, and preventing in this way the tendency they have to become drawn during the early months of the year. More seed should now be sown for successional crops; it is better to sow frequently and to utilise only the thrifty plants than to depend on less frequent sowings, and starve them by confinement to small pots too long. An eye should be kept on the occupants of all fruit-forcing houses, with the object of detecting the first signs of insect attacks, as it will not do to give these any grace. Cherry and peach trees are especially liable to attacks from aphides; but gardeners of the present day have much to be thankful for in the excellent insecticides which may be always at hand for the destruction of these pests without doing any injury to their hosts. Fumigation, which is now such a pleasant function that there is no excuse for putting it off after an attack of insects is noticed, used to be a horror and a danger rolled into one. I find, too, that fumigation, or rather vaporisation, under the new methods can be safely and successfully carried out in houses that could not be made to hold tobacco smoke long enough to kill one-third the insects they contained.—J. C. TALLACK, *Livermere Park Gardens.*

R.H.S. AWARDS.

IN my search through the 1897 awards I overlooked the F.C.C. to Cymbidium eburneum. I was not present at that meeting, but the plant received the award after our custom of granting it to old plants when they are worthy of it. Our records do not contain any evidence of the granting of the award to C. eburneum previously. In like manner the others you mention (January 25, 1898) received their awards. Were Cymbidium eburneum to appear now as a new orchid it would at once receive an F.C.C. Therefore, why not place it in the list, though an old plant, in its proper place, for the benefit of those to come who consult the R.H.S. records for comparative merit? As a matter of fact the whole question of certificates wants remodelling and widening, for orchids have enlarged their domain to such an extent that they have almost outgrown their relation to the pair of certificates we have to grant. The work of the committee is no sinecure, and as it is voluntary and heterogeneous, some error is sure to creep in. I should like to ask if the council *does* review the awards we recommend.

Rosefield, Sevenoaks. DE B. CRAWSHAY.

[As we understand the matter, the object of the Royal Horticultural Society in instituting awards for meritorious plants, flowers, fruits, and vegetables was to confer such distinction on meritorious introductions as would indicate to their Fellows and others interested that they were by reason of their distinctness and high quality deserving of general cultivation. Assuming this to be the object, we fail to see that any useful purpose is served by granting certificates or awards of merit to subjects with which the general body of cultivators are fully acquainted. As no cultivator requires a certificate to be conferred upon the Black Hamburgh or Muscat of Alexandria grape for the purpose of showing him that the variety is sufficiently meritorious to be planted, so we may assume no orchidist requires a certificate to be granted for Anguloa Clowesi or Cymbidium eburneum to assist him in determining whether or not he will add the species to his collection. We readily admit that either of these orchids would be certificated were they to be introduced at the present time, and the distinction would be well deserved. But as they would in that case be unknown to the general body of cultivators, the award would stamp it as possessing merit of a high order, and thus serve as a guide to intending purchasers. To those who fail to appreciate the principle involved in the question at issue, it may appear an anomaly that meritorious subjects which have long been under cultivation should not have distinction, while recent introductions, that in their way are not more valuable, have awards made in their favour; but when the object of the award is properly understood it at once becomes apparent that the certificating of plants that have long been in cultivation, and are generally known, is unnecessary and undesirable. The Floral Committee at one time gave certificates to generally known plants, in some instances to hardy perennials obtained for a few pence, but some years since they abandoned the practice, and in the interest of the Orchid Committee, we trust that body will limit the granting of certificates and awards of merit to plants that are new or not generally known.—ED.]

The Fruit Committee of the Royal Horticultural Society have awarded already this year three first-class certificates to fruits. But such awards would hardly have been so numerously made had the varieties been of indifferent merit, and ripening in November rather than into the new year. Every variety, whether of apple or pear, that shows fine keeping qualities and excellent quality in January, February, or later, is highly prized, because at such periods of the year really good ones are scarce. The new pear, President Barabe, was in fine condition in January, and the old Passe Crasanne, shown on February 8 in such splendid condition, by Mr. Woodward, hitherto never certificated, was even finer and more luscious. Even if it be a somewhat indifferent cropper, at least it is, when well grown, a splendid pear. The new apple, Lord Hindlip, at least new in name, though old at Hindlip Hall, is also an undoubted excellent desert variety, and should soon be widely cultivated.—A. D.

THE SHERWOOD SILVER CUP FOR ANNUALS AND BIENNIALS.

THE details of the competition for the Sherwood Cup that are given on page 48 of the R.H.S. "Arrangements, 1898," do not appear to some people sufficient, and various applicants have asked the following questions, which, with their answers, the President and Council would be greatly obliged by your kindness in publishing for the information of others:—

Q. The contents of each tube must consist of one variety only; am I to understand that Coreopsis grandiflora and C. Drummondi, or Nasturtium Cloth of Gold and N. Crimson King, and so on, may *not* be exhibited in the same tube? *A.* They may not

Q. Are the tubes "not to exceed three inches diameter at the top side"? *A.* They must not exceed.

Q. "The vases must be provided by exhibitors, and must not exceed six inches in diameter inside"; does this apply to the "plain glass vases" only? *A.* Yes; the tubes must not exceed three inches, nor the vases six inches.

Q. Who provides the tubes? *A.* The exhibitor, unless he is content with the stoneware jars the society provides at all times.

Q. Will Regulation XI. be enforced: All specimens must be the *bonâ fide* property of and grown by exhibitor? *A.* Yes.

Q. Must exhibitor stage—*i.e.*, arrange his own exhibit, or may he call in professional help? *A.* A special person may *not* be procured for this special purpose; exhibitor or his gardener, or some member of the family of either, must arrange the exhibit.

Q. Can the exhibit be repeated? *A.* Yes.

Q. Will other foliage be allowed? *A.* Only the foliage of the variety itself.

Q. May grasses be mingled with flowers? *A.* No.

W. WILKS, Secretary R.H.S.

THE BUSH HILL PARK NURSERIES.

SOMEWHERE about the year 1840 Mr. Hugh Low commenced business as a nurseryman, and under the title of Messrs. Hugh Low and Co. the business created by him has for a very long period been among the foremost of its kind in the United Kingdom. The nursery was established at Clapton, and grew so rapidly that Mr. Hugh Low found it too much for one person to properly control, consequently he endeavoured to persuade his son, now Sir Hugh Low, to take part; but a taste of life in the East was not so easily broken with, and the son stayed to make a great name for himself in connection with Borneo and the Straits Settlements. Another son, however, was persuaded to leave the East India merchant service, in which he was then engaged, and come home to assist in a gentler art than that of roving in the East. This son, Mr. Stuart Low, eventually became head of the Clapton firm, and he in turn has been succeeded by his three sons, Mr. Hugh, Mr. Stuart H., and Mr. Edward V., and of these only the two latter remain, but having been brought up in the trade they conduct the affairs of this very large concern in a most efficient manner. As London grew and spread its grimy self, octopus-like, in all directions, it gradually enclosed the once open suburb of Clapton, and it became evident that to successfully compete with other firms the establishment of Messrs. Low and Co. must be carried farther afield. After a careful consideration of sites an outlying part of Enfield was selected, and the admirable manner in which everything has thriven there proves conclusively that the selection was a first-rate one. Another reason for opening a branch nursery was that there appeared little chance of renewing the lease at Clapton, as such a slice of land would at the conclusion of the lease be a most valuable building estate. So year by year, without any undue haste, various departments have been drafted from Clapton to Bush Hill Park, until, a fortnight hence, the head-quarters of the firm will also have been removed thither.

The lease at Clapton does not run out for a few years yet, and the nursery there will be utilised for holding the immense stocks of palms, aspidistras, aralias, and other subjects, known technically as "furnishing stuff," which this firm raises and cultivates so successfully. But for choice stove plants, climbers, cyclamen, New Holland plants, soft-wooded plants, heaths, roses, fruit trees, and last but not least, the orchids, we shall in future turn our faces to the north-east; forgetting that Low and Clapton were formerly inseparable names to horticulturists, but remembering that half an hour's run from Liverpool Street will bring us to Bush Hill Park Station, and three or four minutes' walk will then bring us to the nurseries and headquarters of Messrs. Hugh Low and Co. Here one will find a town of glasshouses covering an area of over four acres; not a house is less than one hundred and twenty feet long, and some must be fully thirty feet wide, and thirty feet longer. All are built in modern style with large panes of glass, so that the largest possible amount of light is received by the occupants. There are about ninety houses; it is not well to give a definite number, for "about" will allow of expansion, and the eighty-seven houses the writer counted may have increased to ninety-three or ninety-five a few weeks hence, and some critical reader and visitor may question the correctness of the figures. The houses at Bush Hill Park grow by sixes or eights, and there is no dawdling when a block is commenced.

When commenting upon such an extensive establishment it is not easy to know where to begin, but let us commence with the cyclamen, for who has not heard of Bush Hill Pioneer, the new crested form that created so much surprise a couple of years ago? Here is a large batch of fine plants and all picked varieties for seeding; they show the cresting along the centre of the segments in a remarkably distinct manner, and prove that in the creation of stock the firm has not been led away by inferior forms for the sake of meeting the demand. Naturally, a large number of crosses have been made between the very best of the Pioneers and cyclamen of other colours, and so far the results are most promising. Bush Hill Pioneer was the result of at least six years' careful selection. The Messrs. Low do not as a rule name their cyclamen, but they have handsome strains of white, one, known as Majestic, being especially good by reason of its purity and the exceptionally broad segments to its large flowers. Then there are batches of deep crimson, very distinct and vivid scarlet, bright rose, deep and rich plum colour, salmon, and other varieties, not forgetting a marked progress in the direction of large and sweetly-scented flowers. Passing on one peeps into long low houses of seedling cyclamen and hears a matter-of-fact statement from the guide that this contains eleven thousand, that thirteen thousand, and so on. When you have heard thousands and tens of thousands tossed merrily about by the various departmental foremen you conclude that figures are a bit of a nuisance, and that the sense of sight gives you a better idea of quantity than do statistics. Carnations of the various winter-flowering types are next passed in review, there are battalions of J. P. Rugus, Daybreak, E. G. Hill, Franco, Miss Joliffe, and a whole regiment of the glowing Winter Scarlet, a variety that is practically perpetual, for new shoots take the lead as others finish flowering. The hydrangeas are very effective though only the buds are as yet to be seen nestling amid the ample and rich green foliage; there is a good batch of the form with variegated foliage and also of the black-stemmed variety known as H. cyanoclada. Marguerites are a grand stock, and one can quite understand that they will soon be disposed of. Decorative pelargoniums occupy several houses, they are grown very cool and on an ash floor, and not fed until the buds set, so that fine stocky specimens are produced; Digby Grand, W. H. Smith, Mrs. Gladstone, Masterpiece, Mabel, and Miss Wetherell are among the favourites, judging by the stocks of them.

Ferns are present in sufficient quantity to stock a moderate-sized nursery, and in addition to large batches of popular kinds such as Pteris cretica majus, P. serrulata cristata, P. tremula in variety, P. Torrancei, P. internata, P. Wimsetti, Asplenium laxum-pumilum, A. nidus-avis, Adiantum cuneatum, A. c. grandiceps, A. Bausei A. Williamsi, A. formosum, &c., there is a large and growing collection of lesser known kinds. Gymnogrammas, nephrolepis and davallias are specially well represented, and among the latter D. Mariesi grown in round masses and like balls of delicate frondage were very attractive suspended from the roof. The popular Aralia Sieboldi and Aspidistra lurida, both of them in green and variegated forms, are models of good culture. The best dracænas are grown by the thousand, and there are whole forests of Ficus elastica that will be turned to better account than even that of the production of india rubber. Many a gardener would be the envy of his neighbours did his houses contain such examples of the handsomely variegated Dracæna Doncetti as here are seen. In tropical heat you wander through groves of Pandanus Veitchi in all sizes, there are bushes of crotons resplendent in green and gold or smaller plants suitable for table decoration or the foundation of exhibition specimens, and the air is fragrant with the scent of Jasminum gracillimum. Bougainvilleas, allamandes, dipladenis, stephanotis, and others are represented by first-rate specimens that would cover a lot of space or make handsome balloon specimens. Gardenias, large and small, jacarandas, Ficus Parcelli, Heliconia illustre, Aralia filicifolia, A. Veitchi, A. gracillima, A. leptophylla, marantas, caladiums, asparagus in variety, nepenthes and a whole host of stove subjects comprising one of the most varied collections seen of late are here represented by thrifty plants such as a gardener loveth.

Turning to another department, you are soon amid heaths of all sizes, species, and varieties, growing or flowering finely, and in such a healthy state that there is no fear of the Messrs. Low and Co. losing their long-sustained reputation for the management of ericas. It is most interesting to view the houses containing the New Holland plants, and also educational, for as they have shown at many an exhibition, the firm not only keep but they can grow these subjects well, and that in a small and attractive state. Cytisus (genistas) are at present very attractive, the golden flowers giving off a pleasing fragrance ; C. fragrans is most in evidence, but C. elegans is also largely grown as well as the beautiful C. Scoparius Andreanus. Many young gardeners would feel as if transported to a new country, here among correas, diosmas, brachysema, polygalas, metrosideros, chorezemas, aphelexis, Tremandra verticillata, witsenias, eriostemons, genetyllis, Aotus gracillima, &c., &c., all neat plants, and many of them now in flower. Acacias are a great feature, and deservedly so, for they are most elegant when in flower ; A. ovata, A. platyptera, A. cordata, A. Drummondi, and A. dealbata are most extensively grown, but there are other interesting species that are good garden plants. Greenhouse rhododendrons with deep green foliage and swelling buds promise a rich harvest. Daphnes, the beautiful and fragrant daphnes, abound, and delight one with their sweetness ; the difficulty at Bush Hill Park is to grow these to any size, not that the firm is incapable of so doing, but because the plants are bought up so quickly. Huge houses fullof azaleas in various stages of progress towards flowering are to be seen, but space limits present mention of more than three of the prime favourites—Deutche Perle, Van den Croyzen, and Fielderi. A beautiful batch of Araucaria excelsa arrests attention as much by its size as thee legance and symmetry of the specimens. Then there are phormiums, ophiopogons, Choisya ternata, boronias of many kinds, but especially B. heterophylla and B. megastigma, coprosmas, cannas, houses of young vines, figs, &c., &c., but we pass now to the orchid department.

Orchids have ever been a great feature at the Messrs. Hugh Low and Co.'s Nurseries, and they take a most important place at Bush Hill Park. There is one very large range of houses connected by corridors, and this contains the cool orchids, and ere now, the phalænopsis as well. Here, too, the firm has made a new departure in the shape of a show house or orchid rockery, where, amid foliage begonias, ferns, and other handsome foliage plants, some of the flowering orchids are placed, and a charming effect is produced. The cool orchids, close by, odontoglossums and oncidiums chiefly, are in the pink of condition, rooting freely into the compost, and what is more to the purpose, bristling with spikes. Here are unflowered thousands of Odontoglossum crispum, O. triumphans, O. luteo purpureum, &c., and buyers may secure another O. c. Queen Victoria, such as the firm showed at the last Temple Show, or some other fine form, and if they do not they will have, at any rate, some good flowers, for there are at present a large percentage of good spotted forms. Like some few other orchid cultivators, Mr. Low believes in early potting for odontoglossums, instead of autumn, and the condition of the plants favours the former *régime*. A goodly number of specimens of Oncidium macranthum attract attention by reason of their immense spikes, some of which have prominent flower buds on them ; these will be a grand sight later on. Odontoglossum Edwardi and O. cirrhosum are well spiked, and there is a large batch of business-looking O. Pescatorei. Here is a batch from which O. excellens is expected, and there a set that should contain O. Wilckeanum or O. Ruckerianum, and, as if to coax them, a few fine plants of these desirable and beautiful orchids are stood among the unflowered ones. One expects to see Cymbidium Lowianum in good condition in the hands of its introducers, nor is one disappointed, for not only are the specimens healthy and of good size, but the varieties are in almost every case first rate, that is to say, they have deep colouring at the apex of the lip. Near by are examples of C. Traceyanum, C. Lowio-eburneum, C. eburneum, and C. Devonianum, all save the latter, in flower, and that only just over. In the rockery the cymbidiums have a fine effect, their long depending spikes suiting that kind of staging. Oncidium splendidum is here quite gay, and a grand orchid it is for late winter ; Lælia cinnabarina also gives a bright touch of colour, and not being a very largely grown orchid it at once arrests attention by reason of its long pseudo-bulbs and deep vermilion flowers. A specimen of Lælia anceps Stella, one of the best of the white forms, lifts its stately blooms aloft on long spikes, and one cannot fail to stop and admire it.

We are next introduced to a block of four houses, all filled with cattleyas—one contains C. Trianæ, one C. Mossiæ, another C. Mendelli, and the last C. labiata. In the first one we noted a plant of C. Trianæ plumosa just coming into flower, and the lovely C. T. Enfieldenæ, white with yellow throat. The specimens of C. Mossiæ vary in size, but as a rule they carry from six to ten sheaths, and promise well ; dotted among them are some specially good forms of Lælia purpurata, while hanging from the roof in two long lines is Cattleya citrina. Cattleya Mendeli, so scarce in some quarters, is here in great plenty, and a house full of semi-established unflowered plants offers plenty of room for hope and speculation ; there are many variations of size and shape in the pseudo bulbs, so that the wiseacres can back their fancy. At one end of the house of C. labiata is a mighty specimen of C. Bowringiana that would startle those who do not grow orchids in larger pots than forty-eight size. One house of C. Percivaliana has not many flowers remaining, but there were sufficient to prove that there are some fine types here. As great a surprise as any was Lælia purpurata, a whole house full of really large specimens full of health and vigour and flower sheaths. Mr. Low now pulls out a special key and we enter other orchid houses, from whence supplies are drawn to fill those already alluded to, and others wherein are choice seedling or varieties varying in size from just perceptible seedlings to good saleable plants. Among the *crème de la crème* we saw examples of Lælia cattleya Pallas, L.c. Nysa, Cattleya Skinneri alba, C. labiata lilacina (the blue labiata) ; Lælia pumila Low's var., a blue form ; L. p. Vine House var., one of the finest ; Cattleya Wagneri, C. Harrisoniæ alba, C. El Dorado, C. intermedia, C. Dowiana, &c. C. Shilleriana is establishing itself nicely, and close by are numerous grand specimens of C. Schroderæ. C. gigas in pans, suspended from the roof, are just the sort of plants for a beginner to start with, as they would give a sure and certain hope of good results. Such trifles as a house full of Odontoglossum grande, not little tiny bits, but sensible plants ; Oncidium tigrinum and O. Marshallianum in bulk ; Sophronitis grandiflora, literally ablaze with colour ; Cypripedium Lawrenceanum, that has given a Hyeanum form ; C. Curtisi, &c., &c., must be passed over and many other orchids left unmentioned, because a mere string of names would serve no purpose. Orchids of all kinds are, however, well managed, and we have very seldom seen such robust batches of cattleyas.

There is much else of interest at Bush Hill Park, for there are nearly fifty acres of fruit trees, and several acres of roses, besides conifers, &c. These, however, we had not time to fully examine, though we saw enough to prove that these departments are as admirably managed as the others. In conclusion, we may emphasise what we have already alluded to, viz., that horticulturists must now think of Messrs. Hugh Low and Co., Bush Hill Park, and go thither in future instead of to Clapton. Bush Hill Park station is on the Enfield branch of the G E.R., and there is a half-hourly train service to and from Liverpool Street.

EXHIBITIONS AND MEETINGS.

THE ROYAL SCOTTISH ARBORICULTURAL SOCIETY.

THIS useful society held its annual meeting in its rooms, No. 5, St. Andrew's Square, Edinburgh, the other day. This was its forty-fifth anniversary, and [illegible] new members were proposed, and there are now on the roll seven hundred and eighty-eight members. It was stated that the income of the society has increased from £285 5s. 8d. to £454 6s. 9d. On the motion of Professor Somerville, seconded by Colonel Bayley, Mr. Dunn, of Dalkeith, was elected an honorary member

The Chairman (Mr. Munro Fergusson, M.P.), in resigning office, spoke of the last few years as the most eventful that had lately taken place in relation to Scottish forestry. The growth of new ideas largely sprang up from their visit to Germany, and hoped that the society would rise to the great opportunities that lay before it. Scotsmen liked to see things done in a proper way. British agriculture was the first in the world, but he would be a bold man that would say the same for our forestry. Most of their great Highland area was fit for forestry and for nothing else, and it was to forestry they must look for the solution of their land and labour troubles. They would never have any large population on the land by creating large or small holdings, or by any agricultural occupation of the greater part of the Highlands. But there was hardly any limit to the population they could bring upon the Highland area if they had a properly developed system of forestry and a well conceived system of manufacturing along with it. He had the privilege of naming his successor, and it was with special pleasure he nominated Colonel Bayley, a gentleman admirably fitted to fill the office. Their work would probably lie in the direction of planting forest experimental areas, which might, by degrees, grow into a forest school. They could begin with the area, and go on to the forest school, for without training their men thoroughly they would not be in a position to go to any government to ask for any great national scheme of forestry being undertaken. Doing full justice to the tact and ability of Scottish foresters, Mr. Ferguson went on to state that they wanted some place where new ideas could be tested, and advanced forestry turned to the best account. This could hardly be done on a private estate. They must have an area where the experiments would be continuous and successive.

Colonel Bayley, on accepting office, thanked all the members for the honour done him, and promised to do all in his power to promote the interests of the society, and added that if in this matter of forest areas, in which they were all so deeply interested, he could render any special service he should be proud if that should mark the period of his presidency. The council had authorised him to state that a draft report had been prepared by Professor Somerville and himself which embodied a scheme. They had hoped that it might have been ready for presentation that day ; but in order that no time might be lost he asked them to give the council power to deal with the report at the next meeting.

Mr. Monro Fergusson, M.P., was cordially thanked for his past services as president, and asked to accept the office of hon. secretary, so that his influence among proprietors, Government officials, and members of Parliament might be preserved to the society. The late president accepted. The election of office bearers, council, and honorary scientific authorities, botanical, chemical, forestry, entomology, geology, meteorology, was then completed.

It was also resolved that the excursion next year should be either to the Forest of Dean or the north of Scotland, and in 1900 to the French Exhibition and some of the French forests.

The following papers were read, and more or less, mostly less, discussed: Grouping versus Mixed Planting (Cullen House), in which grouping was strongly advocated ; the Deterioration of Wire Fences, by Dr. James Kay, forester, Bute ; and a plea for a special organ devoted to Forestry, by Mr. A. McRae, forester, Castleconner, Kilkenny. About fifty members dined at the Royal British Hotel, under the new president, Colonel Bayley.

After dinner capital speeches were delivered in favour of the objects of the society by Mr. John Methven, Councillor Gisliand, Mr. McMillan, Colonel Bayley, Mr. Mather, Mr. James Macdonald, Mr. Erskine-Lonie, and others, and seldom has a more profitable day or pleasant evening been spent by this useful society.

D. T. F.

SCOTTISH HORTICULTURAL ASSOCIATION.

In consequence of the popularity of chrysanthemums in Edinburgh we had a crowded audience at the February meeting in St. Andrews when Mr. J. H. Jones, read a paper on chrysanthemums and their culture. There was not much general business, nor many exhibits, so that it was possible to pass the minutes of the last meeting and elect some dozen new members without loss of time. The president, Mr. Todd, showed a choice collection of daffodils fringed with the golden or yellow Acacia dealbata a rich and graceful blend. And another member some specially fine sprays of the elegant Virgin's Bower, Clematis indivisa, an invaluable decorative climber at this early season of the year for the warm or cool conservatory. We rather expected that some attempt would have been made to show a few blooms of late chrysanthemums, but none were forthcoming, either from the lecturer nor other growers. Hence we found the president, Mr. M. Todd, of Maitland Street, in his usual genial and felicitous terms, soon after half-past seven introducing Mr. Jones. Mr. Jones, after a momentary reference to his modesty, plunged at once into his subject, and proceeded to the first shift, inasmuch as with a few trifling exceptions the great matter of propagation was already over for the season. He, however, remarked in passing that he preferred propagating in boxes or open pits or frames to the usual pots. With a caution against being in too great a hurry to pot, and against potting all [illegible] plants at one time, or potting too many, Mr. Jones said fifty plants often yielded better results than two hundred ; and that we should pot the strongest first, also that we should allow the plants, or rather their roots, to press themselves upon [illegible] before potting them, and this chiefly because unoccupied soil was apt to get in a bad and sour condition. Protesting strongly against overcrowding and coddling, dwelling on the superlative importance of exposing the leaves and buds and flowers to light in all stages, avoiding two of the greatest evils, draught on the one hand and a stuffy atmosphere on the other. As to soil about three-parts of turfy [illegible] one of leaf mould, and one of charred or the ash of chrysanthemum stems [illegible] leaves were the most important. These with the addition of a small proportion of bone meal, crushed bones or soot with some rough silver sand, completed the compost. The latter must be perfect in physical condition as well as composition, though the old plan of squeezing a handful in the hand and allowing it to crumble to pieces again, was given as one of the simplest and surest tests of soil. Firm potting was also insisted on, [illegible] in the case of weakly growth it was best to place the plants in a [illegible] so that the stronger plant might help its weaker brother by using up [illegible] excess of food or water, and so keeping the soil sweet. Condemning [illegible] throughout, Mr. Jones proceeded to describe the various shifts from four-inch pots through six and ten inch and twelve, which, however, need seldom be used. Throughout overpotting must be avoided, as it is found that chrysanthemums flower most freely and most perfectly in rather small pots, the latter being crowded with roots. It was easy to add sufficient food or water at any time, but difficult, if not impossible, to remove any excess of soil from the roots.

Chrysanthemums must never be allowed to suffer or flag for lack of water nor be over-watered. These plants suffer most from dryness at the roots in wet weather. Each fine leaf becomes an umbrella to shade the water off the roots. In examining pots to test their water state it is needful to tap them lower down. For the last shift add a fourth portion of sweet horse manure, such as is used for forming mushroom beds, to the compost. Mr. Jones gave much practical advice as to the time and mode of taking the buds, helping weakly leaves, timing buds for exhibition, showing successfully, &c. As to the latter perfect self-possession, hard work, perseverance, experience, were needful. Mr. Jones was listened to with close attention throughout, and received a hearty vote of thanks at its close.

D. T. F.

HIGHGATE AND DISTRICT CHRYSANTHEMUM SOCIETY.

The annual general meeting of this society was held on the 2nd inst., the President, Mr. H. W. Birks, presiding. The Treasurer, Mr. J. W. McKerchar, read the financial statement, which showed receipts for the past year amounting to £165 6s. 6½d., of which the principal items were: Subscriptions, £63 7s. 6d.; special prizes, £72 14s. The expenditure for the year amounted to £161 2s. 7½d., of which £87 2s. had been awarded in prizes, leaving a balance in hand of £4 3s. 11d. The Secretary, Mr. W. E. Boyce, read the annual report for 1897, which, after relating the success of the last exhibition over any previously held, went on to say that the committee had decided to hold the exhibition for 1898 at the Holloway Hall, and they had every reason to believe that it would be the best exhibition ever held in the north of London. The President, in moving the adoption of the balance-sheet and report, said he thought that they might congratulate themselves that, as a society judged by every test, they had fulfilled their mission. They had not contributed, perhaps, to the "gaiety of nations," but they certainly had contributed to the gaiety of Highgate in providing residents with a two days' exhibition, which, coming as it did in the month of November, proved very acceptable. It was acknowledged on all hands, even by the judges, whom he knew as critical men, that the exhibition was entitled to all the praise bestowed upon it. There was also another test to which many societies would not submit—that of finance—and they had to congratulate themselves that, judged by that test, they came out well; and instead of the statement terminating with the ominous remark that so-and-so was owing to the treasurer, their's showed that there was a small balance in hand. Votes of thanks were passed to the retiring president and officers, also to the vice-presidents and special prize donors. Mr. Birks then introduced Mr. C. F. Cory-Wright, D.L., J.P., M.C.C., as the president for the ensuing year. Mr. Cory-Wright said he did not wish to begin his presidency by finding fault, but he thought they had made a mistake in letting their late president go. Mr. Birks had made it very difficult for anyone to follow him, but, at the same time, he would endeavour to promote the interests of the society as far as possible, and hoped at the end of the year they would be in no worse position. They would even try to be a little better off. The election of officers then took place, Mr. McKerchar and Mr. W. E. Boyce being re-elected treasurer and secretary respectively. Mr. Boyce stated that the schedule was well in hand, and, in fact, ready for the committee to finally settle. The schedule would be larger than last year's, and there was every prospect of a very successful year. The new president gives special prizes to the amount of nearly £12, Mrs. Cory-Wright £2 2s., and in addition he (the secretary) had obtained new special prizes to the amount of £15, including prizes from the leading traders. The meeting closed with a cordial vote of thanks to Mr. Birks for presiding.

READING GARDENERS' ASSOCIATION.

Although ferns are among the most popular of plants with gardeners, both professional and amateur, yet an evening had not been devoted to the subject by the members of the above association previous to Monday last, when Mr. Powell, foreman at Park Place Gardens, Henley-on-Thames, read a paper before a crowded attendance of members, presided over the President, Mr. C. B. Stevens, in the Club-room, British Workman. Mr. Powell, in introducing his subject, referred to the great popularity of ferns, and to their being grown by every gardener, for no matter how small the garden they were required for, their uses were numerous. They were plants that could be grown under various circumstances, for it was not only in the greenhouse and stove that you saw excellent specimens, but in the cottage gardens in town and country. You very often met with splendid examples of the hardy varieties. After dealing with the kinds most suitable for the outdoor rockery, the greenhouse and stove, and the soils best adapted for their successful culture, he impressed upon the younger members in particular the great advantage and pleasure derived from making a study of the various classes of ferns, especially in the drying and mounting of specimens in books, which would, in after years, be a source of profit and assistance. By the request of the lecturer, Mr. Stanton made some very interesting remarks respecting the various varieties, the growth of the spores, and the fertilisation of ferns, illustrating his remarks by dried specimens of crested ferns; ferns with distinct fertile and barren fronds; ferns showing the various kinds of spore arrangements whereby botanists were able to determine the genera; specimens of peculiar interest, such as the gold, silver, variegated, and filmy varieties, some of which the speaker had collected thirty-seven years ago. A discussion took place bearing chiefly on the culture of Adiantum Farleyensis, in which Messrs. Martin, Turton, Woolford, Neve, Phipps, Bright, Tunbridge, &c., took part. Mr. Woolford exhibited some seedling crested ferns of various forms raised at East Thorpe; whilst Mr. Stanton brought a beautiful specimen of Adiantum capillus veneris (the British Maidenhair), growing on the outside of an Egyptian earthenware pitcher. Six new members were elected.

MANCHESTER AND NORTH OF ENGLAND ORCHID SOCIETY.

The second exhibition of this society for the present year was held at the Coal Exchange, Manchester, on the 10th inst. The committeemen present were Messrs. Thompson, Cypher, Stevens, Schofield, Leeman, Boulton, Gratrix, Johnson, Weathers, Gent, Backhouse, and Greenwood. The display was a good one, albinos were plentiful, and dendrobiums especially well represented. A large number of awards were made.

Mr. Shill, gardener to G. W. Law Schofield, Esq., New Hall, Hey, showed Cypripedium G. W. Law Schofield, and Dendrobium anthocentrum, each gaining a F.C.C.; Cypripedium Lathamianum giganteum and Dendrobium Juno gained awards of merit. Cypripedium villosum giganteum and Denbrobium nobile Amesiæ shorwn by Mr. Johnson, gardener to T. Statter, Esq., Stand Hall, gained each an F.C.C., while the lower award was made to D. splendidissimum grandiflorum. Mr. Eastwood, gardener to H. H. Bolton, Esq., Height Side, Newchurch, secured a F.C.C. for Dendrobium Rainbow, and also showed D. melanodiscus and D. Burfordiense. Some good odontoglossums were shown by Mr. Stevens, gardener to W. Thompson, Esq., Walton Grange, Stone, and of these O. candidissima, O. excellens spectabile and O. nebulosum candidulum merited each a F.C.C., while Cattleya amethystoglossa gained a similar award. Mr. J. Cypher, Cheltenham, had a large display showing Odontoglossum Rossi rubescens, Cypripedium Exul, Zygopetalum crinitum superbum, Cattleya Trianæ Gratrixæ, C. T. superba, Dendrobium Ainsworthi Cypher's var., and D. A. hybrid between D. phillipinense and D. nobile, the latter five gaining awards of merit. An award of merit for Cymbidium eburneum, one of the most popular of orchids, was made to Mr. Robson, Bowdon, who also staged several choice forms of Cattleya Trianæ; Mr. Rendall, gardener to F. W. Swinburne, Esq., Winchcombe, sent several cypripediums, a form named C. Mons. de Curte gaining an A.M. Mr. Edge, gardener to F. Leeman, Esq., West Bank House, Heaton Mersey, had a good show of choice orchids; his Cypripedium Haynaldianum merited a cultural certificate, while an F.C.C. was awarded for Dendrobium nobile Sanderianum. Awards of merit were made to Cattleya Trianæ, C. T. alba, Lælia anceps Williamsi, Denbrobium nobile Ballianum, and Odontoglossum Andersonianum. Mr. Rogers, gardener to O. O. Wrigley, Esq., Bury, contributed cypripediums, C. aureum giganteum gaining an A.M. Messrs. F. Sander and Co., St. Albans, were large exhibitors, and their example of Cypripedium Calyso gained a F.C.C; this firm also secured an A.M. for the following: Cypripedium Fascinator nobile, C. Harrisianum albens, Cattleya Trianæ nobilior, and Lycaste Mooreana. First-class certificates fell to Mr. Hey, gardener to G. S. Ball, Esq., Wilmslow, for Cattleya Trianæ alba and Dendrobium Wardianum ochroleuchum; a white form of the latter gained an A.M. Mr. McLeod gardener to G. Gratrix, Esq., Old Trafford, sent several choice orchids, an A.M. being granted for Cypripedium signatum. Messrs. Peeters, of Brussels, sent specimens of Zygopetalum Perrenondi and Odontoglossum Wilckeanum, both gaining a F.C.C. Mr. Bolton, Wilderspool, Warrington, gained awards of merit for Dendrobium Robinsonianum and Cattleya labiata Boltoni; while the higher award was made to both Dendrobium Wardianum candidum and Cattleya Trianæ.

Mr. Stafford, gardener to Fred Hardy, Esq., Tyntesfield, staged an excellent collection of miscellaneous orchids; these were a great attraction, though none were entered for awards. Mr. H. Greenwood, Haslingden, put up Dendrobium Schneiderianum; as also did Mr. D. B. Rappard, Liscard, Cheshire. Cattleya Trianæ, in variety, came from Mr. G. Allen, Sale.

READING HORTICULTURAL SOCIETY.

The forty-first annual meeting was recently held at the Abbey Hall. The deputy mayor (F. J. Ferguson, Esq.) presided, about a dozen other members being present. The secretary (Mr. W. L. Walker) read the report which stated that the past year proved the most disastrous the society had experienced, entirely owing to the stormy weather prevailing on the occasion of the autumn show. The receipts of admission to the two shows only reached £128 10s. (an amount far below the average of the summer show alone); the smallness of this item will, in order to meet the year's liabilities, necessitate the appropriation of the whole of the reserve fund, the loss on the year being about £141. The wreck of the tent by the gale of September 1, is a still greater misfortune, as it can only be replaced at a cost of £250. The society had to regret the loss by death of several of its most prominent benefactors, including Richard Benyon, Esq., Geo. Palmer, Esq., A. Sutton, Esq., and Mrs. Marsland. Thanks were offered to the Deputy-Mayor for the gratuitous use of the Town Hall on the occasion of the autumn show, whereby many of the visitors were enabled to enjoy the music of the two military bands which had been engaged. The accounts, as compared with 1896, showed a decrease in the working expenses of about £80. One of the judges has generously returned his fees.

Herbert Benyon, Esq., Englefield Park, was elected president; Messrs. R. Hewett, and J. O. Taylor, vice-presidents; the following to constitute the executive for 1898, viz.: Revs. Alan Cheales, and F. L. Weale; Messrs. H. G. Cox, H. Dunlop, F. J. Ferguson, R. C. Mount, A. Palmer, J. T. Strange, L. G. Sutton, T. E. Hewett, R. Webb, G. W. Webb, and J. Woolford; a sub-committee to arrange schedule of prizes, date of shows, &c., to be drafted from the general committee. To save their New Zealand £100 bond, it was decided to make an appeal for donations to enable the society to keep on its legs; Mr. R. Hewett starting the list with £10.; Messrs. Sutton and Sons contributing £21.

EXETER AND DEVON GARDENERS' ASSOCIATION.

There was a large attendance at the February meeting of this society, when Mr. F. W. G. Shrivell, F.L.S., gave an address on the experimental culture of vegetables with and without artificial manure. The chair was occupied by Mr. W. Swan.

In his opening remarks, Mr. Shrivell said chemicals in horticulture were an unknown quantity at present, and all he could do was to give them some particulars of what had been done in Kent in the cultivation of vegetables and sometimes fruit. Up to four or five years ago very little was known of the effect of chemical manures upon vegetables. The matter was taken up by Dr. Bernard Dyer, who with himself had conducted a series of experiments and obtained some most interesting results. With regard to this subject they were far ahead of the Germans or the French, and the French Government had voted a large sum of money for their cultivators to obtain instruction in the Kentish experiments. He was not there to tell them that dung was no good, but he would prove to them that dung in itself was a most expensive manure, and that by the use of chemicals in conjunction with dung they would raise the greatest possible crops at the least possible expenditure. The experiments in the first place had been commenced with a light dressing of dung. The constituents of dung included ammonia, phosphoric acid, potash, and lime, which were the basis of plant foods. They wanted to get these substances from chemicals, and he assured them that chemical manures did not run the ground out if properly applied. The cheapest form of chemicals were nitrate of soda for ammonia, super-phosphate of lime or basic slag for phosphoric acid, and kainit for potash. Mr. Shrivell then proceeded to give the result of experiments made with dung and with chemicals. In the case of rhubarb considerably more was grown with £3 worth of chemicals than with £10 worth of manure. With regard to strawberries, the results showed that beyond a certain limit manure was not only thrown away, but it produced leaf instead of fruit. In an experiment with fifty loads of dung, less weight of fruit was obtained than with twenty-five loads, but there was an increase when chemicals were used in conjunction with the twenty-five loads. Beyond that there was a loss. With cauliflowers the use of chemicals had given them a larger crop, earlier produced, and of better quality. Dung was of great assistance in places where they had a low rainfall, it was an assurance against drought, but it was not of such great consideration in a place like Devonshire. In reply to the chairman, Mr. Shrivell said up to the present the dressing had been applied each year, but as they went on they would try to see how long the effect of the chemicals would last. With root crops they obtained from 33 to 50 per cent. more with the assistance of chemicals than by dung alone. The use of chemicals made the manure much more valuable than it was by itself. The lecture was followed by a brisk discussion, and at the close a hearty vote of thanks was accorded the lecturer.

SHEFFIELD CHRYSANTHEMUM SOCIETY.

This body held its annual general meeting at the Museum Hotel on February 2, Mr. J. G. Newsham presiding. The balance-sheet showed an increase to the balance in hand of nearly £16, making a total of over £100. It was decided to put £50 of this amount aside as a reserve fund, experience having shown that unless a provision of this kind is made the society may lose the whole of the balance in the event of inclement weather at the annual show. The Gardeners' Provident Fund in connection with the society, is in a sound financial condition, and has a balance of £58 12s. The following gentlemen were elected officers for the year: President, Mr. C. E. Jeffcock; hon. treasurer, Mr. Henry Broomhead, F.R.H.S.; trustees, Mr. J. G. Newsham and Mr. H. Slaney; auditors, Mr. J. Haigh and Mr. W. Redmill; librarian, Mr. R. Gascoigne; collector, Mr. W. Carlton; secretary, Mr. W. Housley, 177, Cemetery Road; curator, Mr. T. Brewer. The chrysanthemum show is to be held on November 11 and 12, and schedules can be had from the Secretary, Cemetery Road, Sheffield.

The monthly meeting of this society was held at the Museum Hotel, Orchard Street, last Wednesday, Mr. John Haigh presiding. The exhibits were tulips for professional gardeners, and other flowering plants for amateurs. Some very good specimens of tulips were shown by Messrs. Artindale and Son, not for competition. The varieties were Proserpine, Artus, and Keizer Kroon, a certificate of merit was awarded for culture. Mr. W. H. Winter gave an admirable essay on Plant Life, dealing with the different organs, fertilisation, propagation, and also the methods of feeding. An interesting discussion followed, and the meeting concluded with a hearty vote of thanks to the essayist.

BECKENHAM HORTICULTURAL SOCIETY.

This society has arranged an interesting course of lectures to supplement the ordinary weekly meetings, at which various papers are read and discussions follow. The first lecture took place on Friday evening, when Mr. James Martin, of Messrs. Sutton and Sons, Reading, gave a most interesting and instructive discourse on the gloxinia. The meeting was held in the Public Hall, and the room was well filled by gardeners employed in the neighbourhood. The lecturer reviewed the history of the gloxinia from its earliest known date—1739—and described its evolution to the present state of perfection to which this beautiful plant has been brought. The chair was taken by Mr. H. J. Jones, of Lewisham. There was a charming group of cyclamen, brought by Mr. T. Croswell, which drew from both chairman and lecturer the highest compliment. Votes of thanks were passed to the lecturer and to Mr. W. H. Bullivant, of Homewood, for lending the plants above referred to.

HORTICULTURAL CLUB.

The twenty-third annual dinner of the club was held on Tuesday 8th, when there was a larger gathering than on any previous occasion, the chair was occupied by Sir J. D. T. Llewelyn, Bart., M.P., chairman of the club, there were also present: Mr. Harry J. Veitch, vice-chairman; the Rev. W. Wilks, the Rev. Joseph H. Pemberton, Messrs. J. Gurney Fowler, and J. Hudson (newly elected members of the Council of the R.H.S.), James Walker, G. Bunyard, G. Monro, C. J. Wise, Peter Kay, Harry Turner, J. Assbee, J. K. Featherby, A. Goodinch Williams, G. Paul, H. J. Pearson, Charles Pearson, Philip Crowley, A. Watkins, J. Sweet, R. Gofton Salmond, H. T. Armitage, R. Pinches, &c., and the secretary. Mr. G. Bunyard arranged for an excellent selection of instrumental and vocal music to be given during the evening, an admirable dessert was provided by the kindness of Messrs. G. Monro, Assbee, and Peter Kay, while the tables were beautifully decorated with flowers and plants from Messrs. J. Veitch and Sons. The usual toasts were given, and altogether a most successful meeting took place, the condition of the club was stated to be very satisfactory, and several new members were added.

MARKETS.

Covent Garden.

SUPPLIES of fruit are moderate, but the demand is keen and prices high. There are large consignments of oranges and lemons, and these meet a steady demand. Flowers are fairly plentiful. Vegetables are becoming dearer.

FRUIT.—American and Nova Scotian apples, 12s. to 30s. per barrel; French pears, 6s. to 9s. per case; pineapples, 2s. 6d. to 7s. 6d. each; English grapes, 1s. 9d. to 3s. per lb.; Almeria, 15s. to 25s. per barrel; lemons, 8s. to 18s. per case; Canary tomatos, 1s. to 1s. 6d. per tray, 3s. 6d. to 4s. 6d. per case; Valencia oranges, 9s. to 18s. per case; Jaffas, 8s. to 11s. 6d. per box.

FLOWERS.—Arums, 2s. to 3s.; carnations, 1s. to 3s.; eucharis, 3s. to 4s.; gardenias, 6s. to 9s.; Lilium Harrisi, 4s. to 6s.; tea roses, 6d. to 1s.; pink roses, 2s. to 4s.; cattleyas, 6s. to 9s.; Odontoglossum crispum, 1s. 6d. to 4s.; tulips, 6d. to 1s.; and tuberoses, 6d. to 9d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; chrysanthemums, 9s. to 18s.; marguerites, 2s. to 4s.; white narciss, 2s. 6d. to 5s.; Roman hyacinth, 4s. to 9s.; daffodils, 5s. to 8s.; mignonette, 2s. to 4s.; pelargoniums (scarlet), 6s. to 8s.; and violets, 9d. to 4s. per dozen bunches; azaleas, 6d. to 9d.; stephanotis, 4s. to 6s.; lily of the valley, 6d. to 2s.; and pelargoniums, 6d. to 1s. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 3s. to 4s. per bunch.

VEGETABLES.—Seakale, 10s. to 15s. per dozen punnets; celery, 8s. to 15s. per dozen rolls; asparagus, 4s. to 10s. per bundle; mushrooms, 6s. to 8s.; eschallots, 2s. to 2s. 6d. per 12 lb.; parsley, 2s. to 2s. 6d.; carrots, 2s. to 3s. per dozen bunches; cabbages and savoys, 3s. 6d. to 5s. 6d. per tally; English onions, 6s. to 7s. per cwt.; Valencia, 7s. to 9s. 6d. per case; endive, 1s. to 1s. 6d.; lettuce, 1s. to 1s. 6d.; cucumber, 4s. to 8s. per dozen; Brussels sprouts, 2s. to 3s. per bushel; Italian cauliflowers, 3s. to 4s. per basket; forced rhubarb, 2s. to 2s. 6d. per dozen bunches; Malta new potatoes, 18s. to 20s. per cwt.

Borough Potato Market.

A comparatively quiet trade continues at recent prices.

Dunbars, 110s. to 120s.; Hebrons, 85s. to 100s.; Snowdrops, 80s. to 90s.; Bruce Maincrop and Sutton's Regents, 80s. to 85s.; Reading Giants and Saxons, 80s. per ton; Belgians, 3s. to 3s. 9d.; Germans, 3s. 6d. to 4s. per bag.

THE BEST GUIDE to the garden for the whole year is the "Gardening Year-Book," containing practical articles on the cultivation of Flowers, Fruit, Vegetables, &c. Price 1s. "Gardeners' Magazine" Office, 4, Ave Maria Lane, London.—[ADVT.]

LAW.

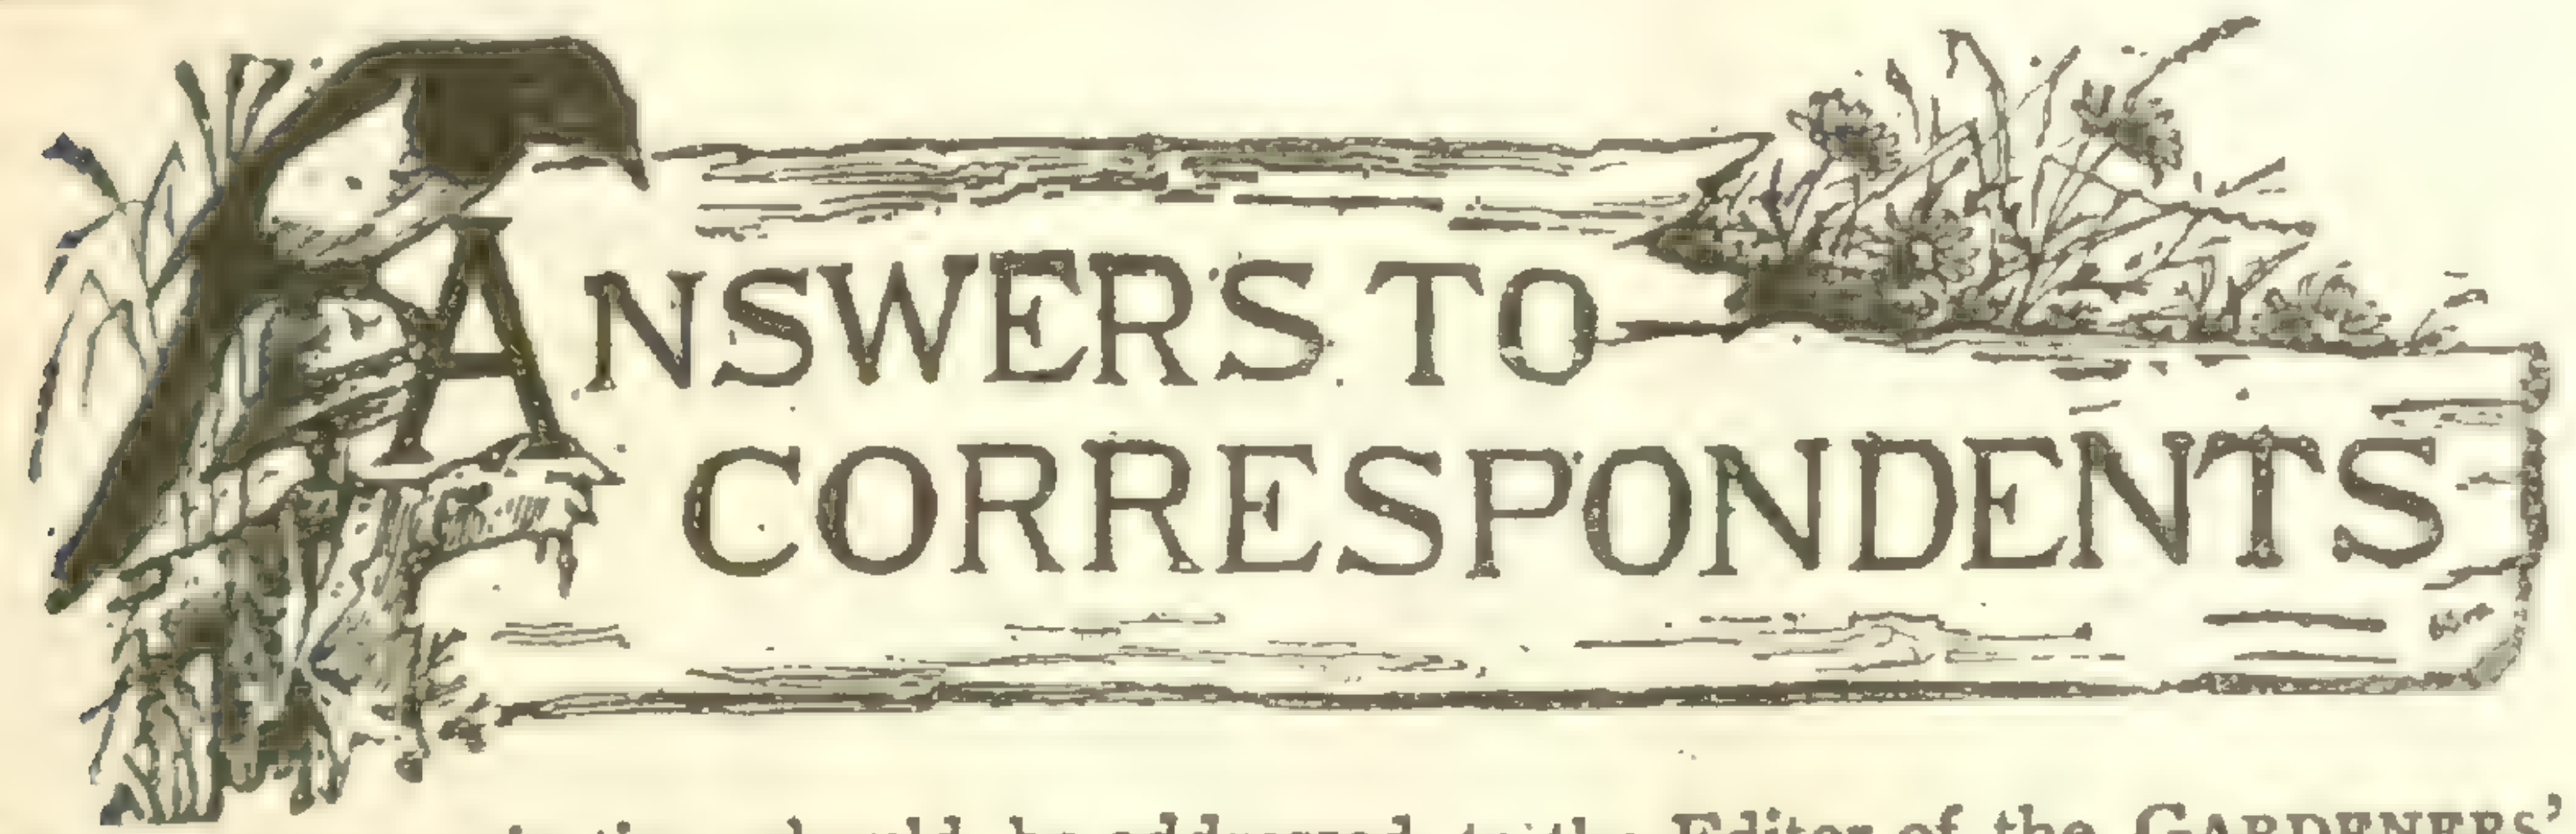
SALE OF A CATTLEYA.

ON Monday last, the 14th inst., an appeal in the case of Ashworth *v.* Wells was heard in the Court of Appeal, before Lord Justice A. L. Smith, Lord Justice Chitty, and Lord Justice Collins. This was an appeal from an order of a Divisional Court (Mr. Justice Day and Mr. Justice Lawrance) on an appeal from the Manchester County Court. The plaintiff, an amateur orchid grower, bought an orchid at a sale of the defendant's collection of orchids in June, 1895. It was entered in the catalogue as a "Cattleya Aclandiæ alba, seven bulbs and three leaves, the only known plant," and it was knocked down to the plaintiff for twenty guineas. It had never flowered while in the possession of the defendant, and it turned out after two years' cultivation by the plaintiff to be not an alba or white variety of Cattleya Aclandiæ, but the ordinary purple form, which was worth only 7s. 6d. The plaintiff having brought this action for damages, the defendant admitted liability, and paid into Court £23 2s. The County Court Judge held that if the plant had been an alba it would have been worth more than £50 at the time of the sale, but that until it showed its real nature there was no probability that any orchid-grower would give more than twenty guineas for it. He thought that the sum paid in was enough, and gave judgment for the defendant. The Divisional Court thought that the case ought to be tried again, and sent it back to the County Court Judge. The defendant appealed.

Lord Justice A. L. Smith said that, in his opinion, judgment ought to be entered for the plaintiff for £50. There had been a public sale by auction of a collection of orchids belonging to the defendant. It was admitted by the defendant that one of the entries in the catalogue constituted a warranty with regard to a certain orchid. It was as follows:—"Cattleya Aclandiæ alba, seven bulbs and three leaves, only known plant." The purple cattleya was a common plant; the white cattleya was exceedingly rare, or rather, if the catalogue was correct, unknown. The plaintiff attended the sale and bought this orchid on the faith of the warranty for twenty guineas. If it was purple it was only worth 7s. 6d. Now what was the nature of the warranty? In his judgment, according to the true reading of the clause in the catalogue, it was a warranty by the defendant that this orchid, when it flowered, would flower white. There was no warranty that it would flower, or even that it would live. The plaintiff therefore had to wait the ordinary course of events for the plant to flower, and in two years' time it did flower, not, however, according to the warranty, but it flowered purple. The plaintiff complained that there had been a breach of the warranty, and brought this action in the County Court for £50. The defendant paid into Court the sum of twenty guineas, the price which the plaintiff had paid for the orchid, and a sum of two guineas for interest, and a further small sum to cover the costs of the plaint. The real question in the case was whether the plaintiff was in law entitled to any damages beyond the twenty guineas which he had paid for the plaint on the faith of the warranty. The County Court Judge thought that the plaintiff was not entitled to any further damages, and he gave judgment for the defendant on the ground that the sum which he had paid into Court was sufficient to satisfy the plaintiff's claim. The Divisional Court had made an order that the case should be sent back for a new trial. In his opinion it should not go back for a new trial, but judgment should be entered for the plaintiff for £50. At the trial there had been abundant evidence, which was uncontradicted, that the orchid, if it was white, was worth one hundred guineas. But no one could possibly tell at the time of the sale whether it was white or not. The plaintiff had to wait to find that out, and after waiting he found that the warranty was broken. Under those circumstances, What were the damages to which the plaintiff was entitled? It was said that he was only entitled to such damages as he could show that he had suffered at the time when the article was delivered. In the great majority of cases that was the proper rule, the market value being the chief factor to be considered. But the plaintiff in this case was, in his opinion, entitled to prove that he had suffered special damages, and he might wait a reasonable time to see what those damages were. This orchid could not properly be said to have any market value at all. The County Court Judge found as a fact that, if it was an alba, it was at the time of the sale worth more than £50. The evidence showed that it would have been worth more than £100, but with regard to the jurisdiction of the County Court it was sufficient to say it was worth more than £50. That finding seemed to him to dispose of the case, and he thought that the County Court Judge ought thereupon to have given judgment for the plaintiff for £50. But he went on, and proceeded to find further that until the plant showed its real nature there was no probability that any orchid grower would give more than twenty guineas for it. He thought the County Court Judge, in coming to this further finding, had misdirected himself. The warranty was that, when the plant flowered, it would flower white. The plaintiff was entitled to wait until it did flower, which did not happen for two years, and it was a mistake to say, when it did flower and the warranty proved to be broken, that the measure of damages was to be regulated by what the plaintiff had given for the plant two years before. The price which he gave was no criterion of the loss which he sustained. In his opinion, therefore, the appeal failed, and judgment must be entered as he had stated.

Lord Justice Chitty said it had been argued that the only damages which had been sustained were represented by the difference between the value of the plant at the time of the sale and what would have been its value if it had answered to the warranty at the time of the sale. He thought that this was not a case in which that general principle could be applied. This was a special kind of warranty, and, in his opinion, the plaintiff had shown special damage. He thought the first part of the finding of the County Court Judge settled the question, and that what followed gave rise to the difficulty which had been felt in the case. The plaintiff could not bring his action until he had ascertained that the orchid bore a purple flower. He therefore agreed with the judgment which had been delivered by Lord Justice A. L. Smith.

Lord Justice Collins said he agreed in the main with his learned brethren, but he felt some difficulty in coming to the conclusion that the County Court Judge, in whose hands the question of damages rested, and who had found £20 to be the sum to which the plaintiff was entitled, had misdirected himself. The general principle seemed clear enough—that in cases of breach of warranty the measure of damages was the difference between the contract price of the thing sold with the warranty and the market price or real value if it could be ascertained, and any special damages following from the buyer acting on the warranty might be added. Here the distinction seemed to be between the value of the plant with the contingency that it might flower and the value of the plant when it had flowered. If the County Court Judge meant that, and came to the conclusion that the true value of the plant with that uncertainty was no more than the money paid into Court, he felt a difficulty in saying that he was wrong. But he was satisfied that they were not giving the plaintiff too much, and he would not differ from the judgment which had been delivered.



ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forth coming exhibitions and meetings, and are requested to advise us concerning change of dates

Moles and Mice.—R. B. O., Carnarvon: To get rid of these pests you will have to resort to traps in both instances, especially as you are not allowed to keep a garden cat to kill the mice. We suggest that you obtain a pair or two of owls—young ones—and feed them, so that they will not go far away; they will assist you in a most marked manner to reduce the pests.

Failure with Tulips in Pots.—A. S. B., Essex: It is probable that the tulips were frozen when in the cold frame; they were then considerably advanced, and the moisture collecting in the cup formed by the leaves was turned to ice, or at least, the surface of it was, with the result that the peduncle was damaged. When placed in heat there was not a proper sympathy between the roots and the flowers, owing to the damage below the bud, and so a collapse followed. The Parrot tulips are not the best for forcing.

Potatos in Pots.—A. I. F., Bath: Where there are vineries or peach-houses it is not a difficult matter to grow a few potatos in pots so as to secure a few early dishes of new tubers. Select a naturally early and short-topped variety and place the seed tubers on end in a shallow box, with some leaf-soil or cocoa-fibre refuse under, over, and between them; stand the box in a light position in a temperature of about 50 degrees for about three weeks before planting, and then they will be nicely sprouted and rooted also. Prepare sufficient ten or twelve inch pots by crocking carefully, use a good loamy compost, and only fill the pots three parts full at planting time. The remaining space should be filled when the haulm is a few inches high. Use a light and fairly rich compost for the top-dressing. Guano is a fine manure for potatos grown in pots or boxes. Do not attempt to force growth in a close damp house, or the result will be a lack of tubers. Light and air, with a moderate amount of moisture at the roots are essential for potatos in pots. Two sets in each pot will be sufficient.

Green Primula Flowers.—P. T. B., Sydenham: The specimen sent was a most interesting one, for we have never seen such a fine development of green foliaceous flowers in the primula before. Such flowers, of course, but go to prove that floral organs are but differentiated leaves, though in this case the reversion is very wonderful. Such a plant would have no commercial value, but it is worth perpetuating as a curiosity. If you can save seeds do so and experiment with them; most of the flowers sent had aborted stamens and stigma, so that there is a probability of your not being able to obtain seeds.

Double Cineraria.—A. B., Aston: The cineraria you have seems to be rather a semi-double than a double form, so there should be no difficulty in obtaining seeds from it. Place the specimen in a light house where the atmosphere is kept drier than in a cold frame; see that it does not want for moisture at the roots, however, and allow it all the sunshine that appears, and then there should be no difficulty in saving seed. You could also perpetuate the variety by means of the sucker-like growths that arise from the base; a little top-dressing of rich light soil as these appear will induce them to push freely, and then they can be removed, inserted in small pots in sandy soil, and struck in a close pit. After once rooted they must not be coddled, however.

Failure with Celery.—R. B. O., Carnarvon: It is probable that the ground in which the celery was planted had not been properly worked and manured previously. Then, after planting, an abundance of water was given which washed away most of the goodness in the soil, and caused the celery to grow tall, but with little substance in the stems to allow them to winter well. The ground must be very rich and substantial, and water must be given the celery, if the weather is at all dry; and when a few waterings have been given, then liquid manure of moderate strength must be provided until earthing-up commences. It is a mistake to earth-up celery loosely, for this will allow the early winter rains to penetrate and cause irreparable damage. Earth-up firmly, and finish off the ridge so that the rain is shed from the plants.

Wood-lice in Tomato House.—Subscriber: As wood-lice are natural scavengers, it is a great advantage to growers to keep the houses clean, so that none of the pests are harboured by dead leaves, decaying wood, &c. Toads and tomtits will assist in a most able manner to reduce the lice, and consequently should be encouraged. Take a number of dirty pots, some dirty crocks, and dirty, but dry, moss, mix the two latter and place inside the pot, adding a slice or two of cold boiled potato. Place this as a trap in the haunts of the wood-lice and cover lightly with dry moss. Kill the pests by emptying the contents of the dirty pots into a bucket of boiling water; the traps should be emptied at dusk or dawn. The moss and crocks will be available again as soon as dry. Potatos cut in halves, and the inner side partly scooped out, also form good traps, that need examination night and morning. By persisting with these means for a week or two a clearance should be effected.

Violets in Frames—C. B., Wetherby: It is a mistake to take either cuttings or rooted runners of violets for winter flowering too early. May will be found soon enough. Very early propagation results in abundance of foliage and small flowers. In April, when new growth commences, take some leaf mould mixed with a little sand, and place this between the plants. The new runners will root freely, and provide medium-sized crowns for subsequent planting in a border that is cool and moist. Absolute shade all the day is neither necessary nor good for the young plants, but it should be borne in mind that fairly strong loam and a locality where the air is naturally cool and moist for a greater part of the

SELECT NOVELTIES IN SEEDS FOR 1898.
TO BE HAD FROM ALL SEEDSMEN.

BURPEE'S NEW DWARF SWEET PEA, PINK CUPID.
We call special attention to this unique Novelty of American origin. No Novelty of recent introduction has such brightness, beauty and grace combined as PINK CUPID.
Packets of 24 seeds, each 1/-; Packets of 12 seeds, each 8d.

EVERLASTING PEA, PINK BEAUTY (Larhyrus latifolius var.)
An entirely new variety, the colour of which is a delicately shaded pink on the standard, the lacing of the edge being paler than the centre, the wings are deeper pink, of a very rich shade, giving it a very striking appearance. **Per Packet, 1/-.**

PRIMULA FIMBRIATA ROSEA DELICATA.
The colour of this beautiful new variety is a charming and delicate shade of rose-pink. The flowers are large and well fringed, whilst the eye is a bright yellow, showing a striking contrast to the ground colour of the petals. **Per Packet, 3/6.**

NEW CULINARY PEA, HURST'S RELIANCE.
The finest of all second early kinds. **Per Quart, 2/-.**

NEW CULINARY PEA, CAPTAIN CUTTLE.
This superb Pea, growing about 3½ ft. high, is the result of a cross between "G. F. Wilson" and "Evolution." It is a most robust growing sort, and on that account should be sown thinly. The pods are large and handsome, terminating in an abrupt hook, and contain from seven to ten very large deep green peas of excellent quality. It is undoubtedly one of the heaviest late croppers in existence. Awarded full marks of merit by the Royal Horticultural Society. **In sealed Half-pint Packets, 2/6 each.**

NEW CULINARY PEA, THE GLADSTONE.
In Half-pint Packets, 2/- each.

MELON, DIAMOND JUBILEE.
First Class Certificate, Scottish Hortcultural Society, August 3rd, 1897.
This variety is the result of a cross between "Best of All" and "Countess," and is a decided improvement on both these well-known kinds. The fruits are oblong in shape, beautifully netted and assume a pretty golden-yellow when ripe; weight from 3 to 5 lb., flesh greenish-white, flavour excellent, a distinct acquisition for early crops, and will prove a boon to market growers. **Per Packet, 1/6.**

Wholesale only from HURST & SON, 152, HOUNDSDITCH, LONDON, E.

COMPETITION DEFIED!
OUR UP-TO-DATE SEED CATALOGUE
for 1898 proves that our prices are far below any others. We guarantee our Seeds to be
NEW, GENUINE, and RELIABLE.
In dealing with us great benefit is derived, as we do not spend our clients' money in costly advertisements; nor is our Catalogue a work of art, entailing enormous expense (needless to ask who pays for this). We have shown what we can do in the BULB TRADE on the score of economy and excellence, and we shall supply our Seeds on the same basis. Therefore, send for our Catalogue (free), and judge for yourselves.

1898 FORBES' CATALOGUE 1898
(over 150 pages—nearly 150 illustrations) of
FLORIST'S FLOWERS and HARDY BORDER PLANTS
is got up REGARDLESS of TROUBLE or EXPENSE, with the result that it is by UNANIMOUS CONSENT pronounced the most COMPREHENSIVE, most ACCURATE, most RELIABLE, most COMPLETE, and BEST EXTANT.
It gives full and ACCURATE DESCRIPTIONS of everything in the way of FLORIST'S FLOWERS, also COLOUR, HEIGHT, TIME of FLOWERING, and PRICE of all the best HARDY BORDER PLANTS, together with their ENGLISH or COMMON NAMES, and a mass of other VALUABLE INFORMATION that cannot be had elsewhere.
It is, in fact, a veritable REFERENCE-BOOK, invaluable to all growers of these plants, and should be in the hands of all intending purchasers. Free on application.

HAWICK, SCOTLAND.
ESTABLISHED 1870.

FOR SALE, large number of good second-hand and new wrought and cast iron and wood TANKS; all shapes and all sizes; lists and prices on application; enquiries solicited; tanks of all kinds bought.
Apply THOS. W. WARD, Fitzalan Chambers, Sheffield.

time, even in the Dog Days, is the one for these violets, and no amount of watering will produce the conditions on light soil, and where the air is naturally dry and hot. Runners must be kept picked from the crowns, and then when autumn arrives it will be found that well-developed crowns, plenty of roots, and firm foliage have been produced, that will result in abundance of flowers as soon as the plants are established in their winter quarters. Four good varieties for frame culture are Marie Louise, The Czar, Comte Brazza, and De Parme, the latter a useful variety for continuing the supply well into the spring.

Names of Plants.—A. H., Slough: Helleborus viridis.

A. G., Brentwood: 1, Crassula coccinea; 2, not recognised; 3, an Isoloma; 4, a Caladium; 5, a Klenia; 6, Irisine Lindeni; 7, a Campanula. Those not fully named we shall be glad to deal with when you send them in flower, as only under such conditions can they be identified. The caladium is not yet sufficiently developed to be recognised.

C. W. R., Croydon: Apparently a form of Odontoglossum Lindleyanum.

H. H. H., Wadhurst: 1, Cestrum elegans; 2, Senecio Kæmpferi aureo-maculata, formerly known as Farfugium grande; 3 and 4, please send portions of fertile fronds; 5, Nephrolepis exaltata.

Names of Fruits.—R. C., Truro: 1, Blenheim Pippin; 2, Dumelow's Seedling (Wellington).

THE MOST IMPORTANT LESSON Esculapius tried to impress upon his pupils was that the chief trouble afflicting humanity was due to impurities of the blood. All disorders may be traced to this fact, for unless the source of life is free from disease germs it cannot have that strength which is necessary for good health. Holloway's Pills are composed of the most precious herbs and soothing balsams which Mother Earth can offer to her children, therefore they may be relied upon to supply the nourishment that is craved by the system. It is no vain boast to say that this is the most wonderful discovery made in the annals of medical science; they will cure or relieve all diseases.

NATIVE GUANO.

BEST AND CHEAPEST MANURE FOR GARDEN USE.

Price **£3 10s.** per ton in bags. Lots under 10 cwt., **4s.** per cwt., 1 cwt. sample bag sent carriage paid to any station in England on receipt of P.O. for **5s.**

Extracts from 22nd annual collection of reports:—

NATIVE GUANO FOR POTATOS, VEGETABLES, &c.

C. H. TINDALL, Bardney: "Used for Potatos. Result very satisfactory; yield much above average. A splendid manure." G. WATTS and SONS, Bournemouth, report: "Good for general purposes. Grand for all Root Crops, Tomatos, and Cucumbers. Find it so cheap; and it does not exhaust the ground like other manures."

NATIVE GUANO FOR FRUIT, ROSES, TOMATOS, &c.

E. F. USHER, Sidcup: "Potatos and carrots, splendid crops; Peaches, Nectarines, &c., splendid. Should not like to be without it on any consideration." G. STONARD, Gardener to Sir A. T. Watson, Bart.: "Used for seven years for Peaches, Grapes, Tomatos, Cucumbers, Roses, and Chrysanthemums with excellent results."

Orders to the **Native Guano Co. (Limited),** 29, New Bridge Street, Blackfriars, London, where pamphlets of testimonials, &c., may be obtained. Agents Wanted.
